Making Every Pound of Your Coal Count

Thorough combustion of fuel is assured with "Sirocco" Mechanical Draft Fans. And getting the utmost of heat units out of every pound of coal with "Sirocco" equipment helps insure economical operation of the power plant.

Operated with automatic stokers, "Sirocco" Fans (forced or induced) are helping to reduce the fuel bills of hundreds of public service corporations.

Our engineers are particularly well qualified to cooperate with you in selecting the right kind of Mechanical Fans. Write for descriptive bulletin.

Canadian Sirocco Company, Ltd., Windsor, Ont.

"Sirocco" Products

BLOWERS · EXHAUSTERS · VENTILATING FANS · AIR WASHERS · ENGINES

FOR HEATING, VENTILATING, DRYING, AIR CONDITIONING, MECHANICAL DRAFT

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

Waterous

BRANTFORD, ONTARIO, CANADA

WASTED ENERGY

At first glance, the connection between a boiler explosion and a leaking stuffing-box might not be apparent.

The final result, however, whether by a sudden release of energy, or a slow, steady leak, is the same, —heat energy wasted that would otherwise do useful work on the piston.

A loss that can be avoided by the use of a "live" well lubricated packing, securing a leakless stuffing-box with minimum friction and maintaining a glass-like polish on the rod.

For high pressure and superheat try GARLOCK style No. 446 and "Spare the rod."

BOWSER
ESTABLISHED 1885
PISTON-TYPE MEASURING PUMPS

THE LIFE BLOOD OF THE FACTORY

Dirty, gritty lubricating oil will junk your machinery long before its time. **Friction is production's worst enemy,** and wear and tear caused by dirt and grit in oil slowly but surely wears out expensive bearings and other machinery parts.

Clean oil prolongs the life of machinery. Bowser Lubricating and Filtering Systems assure clean filtered oil on all bearings and restore the oil to its original lubricating quality. Try the Bowser Perfected Process of Seepage Filtration.

Installation takes a minimum of floor space.

There is a Bowser System for every oil filtration requirement. Also complete oil storage and handling equipment.

"PALMETTO"

REG U S PAT OFFICE

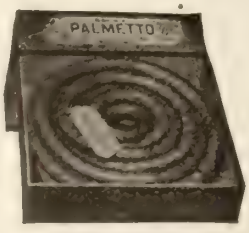
Packing

Rests upon the solid foundation of quality

Made of a grade of material usually considered too good for packing purposes.

However, years of experience have proven that it's this unusual quality that causes "Palmetto" to give longer service than other packings, especially under extreme conditions.

"PALMETTO" is a practically frictionless packing, as it carries an unusual quantity and quality of graphite grease lubricant—keeps the rod perfectly lubricated.



If you don't know "Palmetto" let us convince you with a working sample to test for yourself—no charge.

Let us know the size you can test.

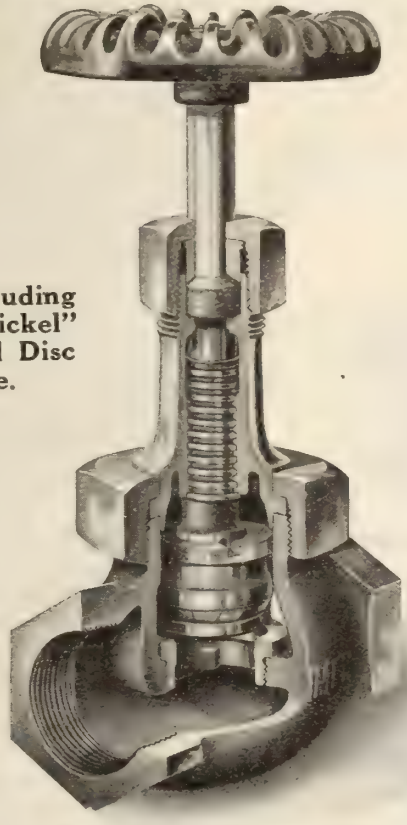
LUNKENHEIMER "Renewo" Valves



All parts including the "Valve-nickel" Seat-ring and Disc are renewable.

Seating surfaces are regrindable.

Medium Pat., Fig. 73.
Extra Heavy, Fig. 16.

Specified by engineers seeking the highest degree of efficiency in operation and maintenance because **"Renewo"** service records are proof positive of their unparalleled value for power plant use.

Users realize there is no substitute for **"Renewo"** excellence — their wear resistance, permanence in the line and low upkeep cost all contributing to economy — the essential to successful plant operation.

The broad scope of the line, including Globe, Angle and Cross, Straightway or Y, and Horizontal and Angle Check Valves, for pressures up to 200 and 300 pounds, covers every requirement.

Carried in stock for immediate delivery by Lunkenheimer Distributors situated in every commercial center. Specify **"Renewo"** Valves and insist on getting what you specify.

PUMPS

This ancient pumping device was only used for local irrigation.

The Egyptian "taaboot"—or barrelmill—is a very curious pumping device. It consists of a long wooden tube, containing a spiral or screw, made of thin wooden laths. As the operator turned the crank, the screw revolved, and literally "screwed" the water out of the river.

One good thing about the barrelmill: It is reliable. The same may be said—in a much more meaningful way—of modern American-Marsh Centrifugal Pumps. These Pumps are made in both single and double suction, solid and split case patterns. Write for Bulletins.

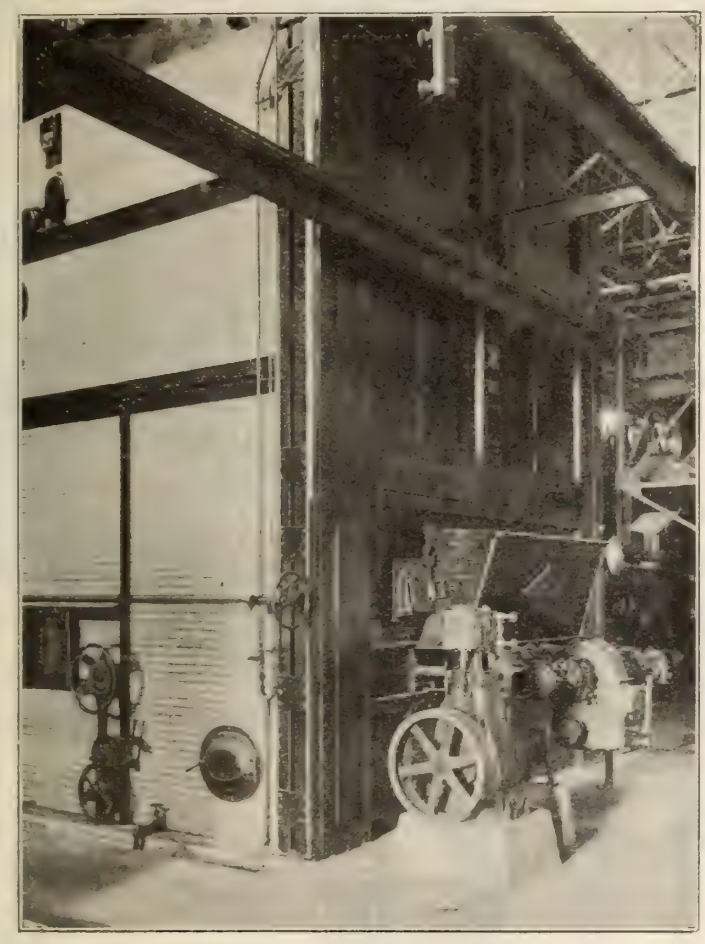
One-Third Less Coal

A large enough saving to interest any power plant manager when every possible means is being used to reduce costs.



"The picture shows one of seven new boilers being installed in the Main Pumping Station of the Waterworks Department, on Eastern Avenue. It is the first of the seven to be completed. Waterworks Superintendent J. A. Hiller declares that the new boilers will save the city $40,000 in the cost of the operating plant. New boilers already in service at the River Pumping Station, California, O., are operating on one-third less coal than was used at that plant with the old boilers."

From *Cincinnati Times-Star*—October 26, 1921

AT the California Station of the Cincinnati Water-Works the new equipment is operating on one-third less coal than was used with the old.

(Note clipping from Cincinnati *Times-Star* below.)

At this station 4-retort

RILEY UNDERFEED STOKERS

fire four 420 h.p. Stirling boilers, furnishing steam for operating the pumps. This equipment was installed under the direction of C. H. Anderson, Mechanical Engineer.

The Riley Stoker effects maximum saving in fuel and labor because it is practically automatic in all its functions. A distinctive feature, the reciprocating retort sides, not only increase efficiency by greatly intensifying combustion, but automatically break up clinkers while the rocker dump continuously discharges the refuse.

Send for the Riley Stoker Catalog, it will show you how to save fuel and labor, two of the most vital factors in your plant.

The Sanford Riley Stoker Company is now prepared to equip new Riley Stokers with coal agitators licensed under the Negus--Tiffany patents.

John Crane

Eight Years of Packing Service
JOHN CRANE Flexible Metallic Packing Shows Greatest Results in Constant Service

Eight years ago Chief Engineer, N. Gross, of the Standard Oil Building, Chicago, installed JOHN CRANE Flexible Metallic Packing in the boiler-feed pump pictured below. Mr. Gross reports packing and pump in good order after eight years and has standardized JOHN CRANE on all service.

JOHN CRANE holds this long service record because of its scientific, practical construction. Made of babbitt foil and graphite, it brings Packing science "The Babbitt-bearing Principle," and while responding to the slightest pressure of the gland never dries out, but remains compressible and will not score rods.

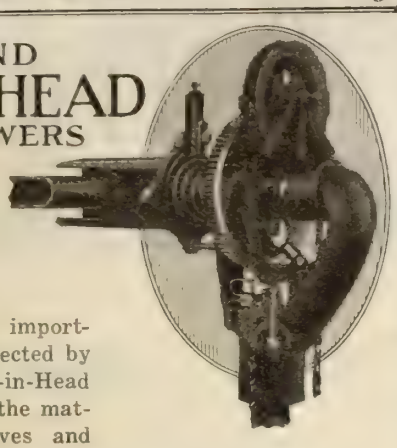
Board of Trade Building, Montreal

Saving 50 to 66% in the Cost of Pipe Valves and Fittings

DIAMOND
VALV-IN-HEAD
SOOT BLOWERS



One of the most important economies effected by the Diamond Valv-in-Head soot blower is in the matter of pipe, valves and fittings on new installations. A saving is made of practically two-thirds in the actual length of pipe required. The elimination of expensive individual control valves in favor of the Valv-in-Head is an important cost consideration. This decreases the initial cost of these items by one-half to two-thirds, and reduces radiation losses from the soot blower lines proportionately.

On a typical six unit installation, with the independent valve system 83 feet of pipe and six 2 in. individual control valves are required. With the Valv-in-Head only 25 feet of 2 in. pipe and no individual valves are required. With this six unit installation the saving in cost of pipe, valves and fittings effected by the Valv-in-Head system is approximately 64 per cent.

The comparisons are:
Using "Bronze body valves, nickel seats and discs"

Independent valve system	**$249.44**
Valv-in-Head system	**90.83**
Saving by latter	**$158.61**

This is only one of eleven important advantages of Diamond Valv-in-Head soot blowers. Others include savings in steam, labor, maintenance, increase in cleaning efficiency, etc., etc.

From an operating standpoint the Diamond Valv-in-Head soot blower is a tremendously better investment than the independent valve soot blower. Among Valv-in-Head operating economies are:

1. STEAM FOR OPERATION: Saving of 50 per cent.

2. LABOR FOR OPERATION: Saving of 50 per cent.

3. MAINTENANCE: Saving of 25 to 50 per cent.

Once installed Diamond Valv-in-Head soot blowers pay for themselves in a few months.

Every Boiler needs a Mechanical Soot Blower and you will save Money by buying the best.

Ask for your copy of Bulletin 287 describing the new soot blower.

The FRICK FLOODED SYSTEM

Is a STANDARD Part of Every FRICK Plant

Its simplicity and dependability have made it a standard known the world over. Its success is unqualified.

It

Simplifies plant operation by reducing the number of feed valves to be regulated.
Increases plant efficiency by insuring uniform operation and giving absolute control of the ammonia.
Adds to plant safety by preventing priming accidents.
Lowers first cost of plant by increasing the heat transfer through the evaporating surface, thus reducing the amount of surface required.

Ask for a copy of our List of Users covering 48 pages of satisfied customers—also your copy of Ice and Frost.

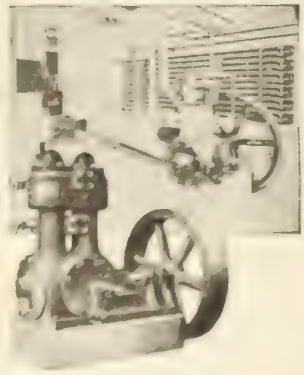
A YORK MACHINE

does not require a skilled operator



DON'T get the impression that Mechanical Refrigeration means complicated apparatus, difficult to understand and costly to operate. You need have no such fears if it's a YORK installation.

A York plant is the embodiment of simple efficiency. No skilled attendant is required. One of our customers says in testifying to the simplicity of his York plant, "It is being operated successfully by an employee who, prior to the installation of the machine, had never seen one nor had any experience in operating one."

Constant attention is unnecessary. The simple regulation of one valve gives any degree of cold you want—freezing, zero, below zero—whatever your business needs may require.

If you want the simplest, most efficient, most economical refrigerating system, you will investigate the York Refrigerating Plant.

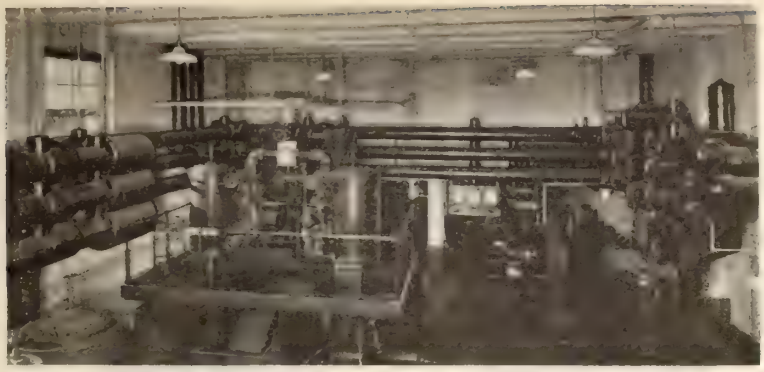
Lost in Transit

THAT IS what happens when refrigeration is carried in bare or poorly insulated lines. Too little gets through: too much is lost along the way.

But not in this plant. The lines are so thoroughly protected with Nonpareil Cork Covering that the refrigeration is brought right up to its work with very little loss. And there is no frost on the pipes and no drip on the floor.



Nonpareil Cork Covering in the machine room of the Hendler Creamery Company, Baltimore, Md.

Nonpareil Cork Covering saves four-fifths of bare pipe losses. It is made in molded sections to conform to pipes of different sizes and fittings of all kinds, screwed and flanged. Nonpareil Cork Covering is easy to install and makes a neat appearance. It is thoroughly moisture—and frost-proof and, correctly applied and cared for, "lasts longer than the pipe."

Have you bare lines in your plant or covering that you know is not right? Send for the 64-page book, "Nonpareil Cork Covering," and a sample. There is no charge or obligation.

Canadian Association *of* Stationary Engineers

Incorporated May, 1887
Incorporated at Ottawa June, 1917

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?
If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.
The undersigned will be very pleased to give any further information required.

The steel container that will bring **PLIBRICO** to you in exactly the right condition to apply.

The Stuff that Stops the Leaks

Nothing saps the coal pile so quickly as air and gas leaks in the boiler setting, bridge walls, or baffles.

Leaks send heat units off up the chimney, cool the gases and cause incomplete combustion. Leaks defeat the whole purpose of the boiler setting, no matter how scientific its design.

Fuel prices compel attention to stopping all leaks, no matter what the cost. The inconvenience and loss occasioned by shutdowns call for the selection of the most *permanent* way of making your furnace *air and gas tight.*

PLIBRICO
JOINTLESS
FURNACE LINING

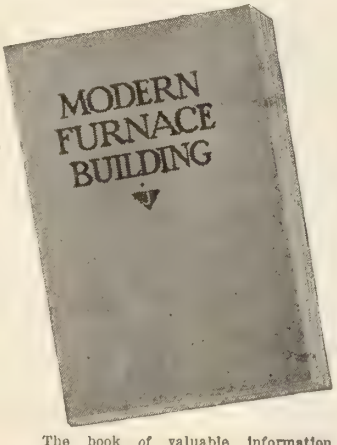
is applicable to any and every type of boiler, and is quickly and easily applied. Many an old setting may be made to give greater boiler capacity, more complete fuel combustion, and smokeless operation by some simple change in baffle walls or other part of setting.

But best results are obtained when the **complete** boiler setting is **PLIBRICO.**

Highly resistant to heat, smooth, strong, durable, **PLIBRICO** is an investment that will bring you many returns on your money in the elimination of shutdowns for repairs, in the saving of fuel, in the reduction of labor.

Our book shown at the right, L-50 on "Modern Furnace Building," will tell you all about **PLIBRICO.** Send for it.

PLIBRICO is delivered only in steel containers of distinctive appearance as shown above and below.



The book of valuable information about **PLIBRICO.** Ask for it.

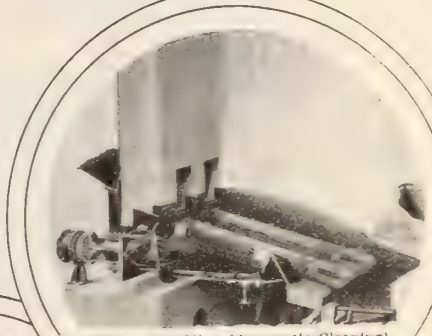
JONES STOKERS

"LIGHT DUTY" "STANDARD" "SIDE-DUMP" "A-C"

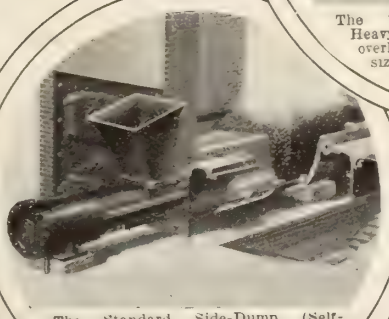
A Type for Every Plant

The Canadian Stoker

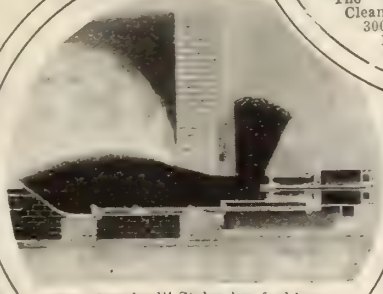
Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co., of America are made available for Canadian power users. Thus this strictly Canadian Stoker is backed by world-wide experience and unequalled engineering ability.



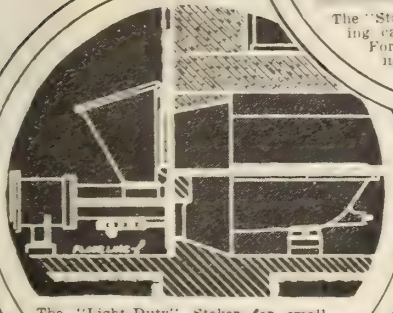
The "A-C" (Automatic-Cleaning) Heavy Duty Stoker—for heaviest overloads and peak loads. No size limit to load or boiler. Get "A-C" Catalog.



The Standard Side-Dump (Self-Cleaning) Stoker. For boilers to 300 H.P. Fuel capacity to 1800 lbs. hourly. Easily installed. Ask for Catalog.



The "Standard" Stoker has fuel burning capacity to 1500 lbs. hourly. For boilers to 200 H.P. For industrial heating furnaces. Get Catalog



The "Light-Duty" Stoker for small plants. Fuel capacity to 200 lbs. hourly. For small plants and for many heating operations. Ask for details.

IN rugged simplicity, in ability to burn all coals at all rates, in economy of fuel and labor—in fact, in all the elements that make the ideal mechanical stoker, Jones Stokers are unsurpassed. The different types of Jones Stokers are described briefly above—completely in separate catalogs. Where shall we mail yours?

Why Not!

Wing nuts on gland bolts

YOU can put wing nuts on your gland bolts if you use Sea Rings in the stuffing box. The day of grinding packing to death with the pressure of an eighteen-inch monkey-wrench is past. Whether or not you use wing nuts, this principle is important.

Nowadays stuffing boxes are merely containers for automatically acting Sea Rings. The reason is simple—*Economy*. All over the country, thousands of Sea Ring packed glands are paying dividends in economical service.

Sea Rings are packed by the pressure they pack against — not by the gland. Cylinder pressure is trapped in the hollow groove, "spreading" it with just enough force to prevent leakage. Thus the Sea Ring adjusts itself, tightening as the pressure increases and easing as the pressure drops. Leakage is stopped with minimum friction.

Sea Ring Packing.
Read how it reduces friction.

Minimum friction—there's where the economy lies. Rods are not scored, packing is not ground to pieces—and, most important, actual power is saved.

You can save money in your plant with Sea Rings. The Sea Ring booklet tells the story, giving the result of actual tests. Let us send it to you.

WAIT STEAM TURBINES

The Acme of Perfection

MANY recent improvements in detail by skilled investigators have resulted in the G. & McC. Co. "Wait" Steam Turbine reaching a high point in efficiency —it is in fact recognized by leading engineers as the acme of perfection in steam turbines. Some of its leading features include in addition to high efficiency—simplicity, ruggedness and economy of operation.

Points of this G. & McC. Co. Machine that should be remembered are:

—The Turbine is entirely automatic.
—No oil or grease cups.
—Stuffing boxes and glands seldom require attention.
—Emergency governor and valve are entirely separate from main governor and valve.
—Interior may be easily inspected.
—Self-lubricating; dust proof; dirt-proof.
—Speed can be changed while running.
—LOW RUNNING EXPENSE AND COST.

How to Make a Boiler Evaporation Test

This Interesting Test, Which Is Looked on With a Good Deal of Awe by Some Engineers, Is Here Explained in Great Detail—The Ease of Performing It Is Simply Demonstrated

By J. A. McGILLIVRAY

IF THERE is one thing above all others that takes the joy out of the engineer's life it is to have an efficiency man come in over his head to conduct a test. Remember I said "over the engineer's head."

In large power plants, the efficiency man is a part of the chief's organization, or vice versa, and there is no room for misunderstanding and no division of authority. There should not be two roads to the superintendent's office. But in isolated power plants the case is different, and in this article I am to be distinctly understood as referring to the latter.

The mere presence of the efficiency man is detested by many an otherwise reasonable engineer, and it is extremely doubtful whether the efficiency department ever accomplishes any lasting good under such circumstances. There is every opportunity for bad feeling and lack of co-operation. If efficiency methods are to succeed at all they can do so only when the engineer in charge will conscientiously cause to be carried out the suggestions of the efficiency man, granting, of course, that the efficiency man knows his business. Where this is not so, it is time to do one of two things, make the engineer in charge the efficiency man as well, or fire him. If he is half as good an engineer as he usually thinks he is, the former is the correct thing to do and the sooner the engineer who is not now acquainted with efficiency methods realizes that he needs that acquaintance in his business, the better for him.

That is one thing that he can thank the war for, (or blame it for, according to his viewpoint). The experiences of the war and its effect on our industrial institutions have started an efficiency wave on the American continent the like of which was never known in the past, and accomplished in one sweep what a few engineers, widely scattered, had been trying to accomplish for a half century; namely, to bring to the attention of plant owners the importance of "Scientific Boiler Room Practice." The engineer no longer has to prod the manager to supply the instruments that make for "scientific operation" of the plant, they are forthcoming when needed, but the greatest need is for engineers who can use them.

Scientific methods have not been adopted in all plants, and those are the ones that suffer most by comparison with modern standards. There is no need for it to be so, since any man who thinks enough of his profession to wish for better conditions can do a lot to better them at small expense, as I will try to show him. Moreover, it might be well for the engineer of the small plant to remember that it may be a stepping-stone to a larger and more modern one, and that the same rules apply to a 10,000 H.P. plant, as to a 10 H. P.

The Object of the Test

The first thing to consider when making an evaporation test is what the object in view is, and to prepare accordingly. There is no mystery about an evaporation test. While it is the most important of all power plant tests, it is the simplest to carry out. Practically all evaporation tests are carried out according to the rules adopted by the American Society of Mechanical Engineers, and those rules will be our guide in what is to follow.

The Preliminaries

There must be some means of weighing the water fed to the boiler during the test. Figs. 1 to 3 illustrate three equipments, either of which can be made up at little expense. No. 1 will handle a test up to 1200 H.P. and by the addition of another barrel above will handle the water for 1500 H. P. The method of measuring the water is to fill the barrels to the small overflow, having in the meantime found out definitely what weight of water is contained in each barrel when full to the overflow (an ordinary oil cask with a hole below the top hoop will hold approximately 400 lbs.). Each barrel is tallied as it is emptied and the weight calculated every hour.

The arrangement of barrels shown may be made permanent or just temporary as the person using the outfit desires. If kept full of water when not in use, the outfit will last till the cows come home. The most important dimensions are marked in. The frame can be made of wood or steel. The whole thing if neatly made, using "flanged fittings," "quick opening valves," for the lower barrels, and a little paint, can be made really ornamental, as well as useful. As arranged in Fig. 1 there is 6 ft. of headroom for the operator who operates the lower valves, but if desired the lower valves can be operated from the upper platform by levers attached to the "quick opening lower valves." The lower barrels are connected to the feed pump or to the injector as the case may be.

Fig. 2 illustrates an outfit that may be used for testing up to 600 H.P. and can be operated by one man. Fig. 3 will test anything below 100 B.H.P. The arrangement shown in Fig. 3 is the most accurate of the three, but has the disadvantage that the boiler feeding will be intermittent.

For weighing the coal a wheel barrow and a platform scale may be used, or if the coal is handy and does not require wheeling a tub made from part of an oil cask can be used. After providing a tally board for keeping account of the coal, and water, a thermometer in the lower barrel for measuring the feed temperature, we are ready to start the test, as far as equipment is concerned.

The next thing to see to is that the ash pits are clean and the fire clean and make a close estimate of the amount of fire on the grate before commencing the test and have a mark on the gauge glass. To mark the gauge glass tie a piece of string around it, and when ready to go ahead, slip the string up or down to the water level, and this is where the water level must be when the test is completed. It must be endeavored to stop the test under as nearly the exact conditions that existed when starting as possible.

While the draft measurement and flue gas analysis are very important, they are not absolutely essential to the success of the test, since if it is found at the end of the test that the efficiency

of the boiler furnace and grate is good, the flue gas couldn't have been far from what it should be, but we will come to that later.

The information tallied during an evaporation test is as follows, and tallied every hour, we will assume certain quantities, for example:

TEST DATA

1	Data and Results of Boiler Test	
	(Width 12 Length 7')	
	sq. ft.	84
	Heating Surface sq. ft.	5000
3	Date of Test .....Nov. 14, 1920	
4	Duration of Test .....Hours	8
5	Kind and Size of Coal (Bituminous R.O.M.)	
6	Steam Pressure by Gauge (ave.) per lbs.	150
7	Temperature of Feed Water...Deg. F.	60
8	% Moisture in Steam or (deg. superheat) moisture	3%
9	% Moisture in Coal .....moisture	7%
10	Dry Coal per hour .....lbs.	1860
11	Dry Coal per sq. ft. of Grate surface per Hr. .....lbs.	22.14
12	Equivalent Evap. per hr. from and at 212 deg. F. .....lbs.	16,331
13	Equivnlent Evap. per hr. from and at 212 deg. F. .....lbs. per sq. ft. of heating surface	3.266
14	Rated capacity per hr. from and at 212 deg. F. ..... lbs.	17,250
15	% Rated capacity developed.....	94.7%
16	Equivalent evap. from at 212 deg. per lb dry coal .....lbs.	8.9
17	Equivalent evap. from and at 212 deg. per lb. combustible coal .....lbs.	12.64
18	Calorific value of 1 lb. of dry coal B. T. U.	10,765
19	Calorific value of 1 lb. combustible coal .....B.T.U.	15,500
21	Efficiency based on combustible .....79.13% (based on coal as fired).....	80.2%
21	Efficiency based on combustible 79.13%	
22	Cost of coal per ton (2000 lbs.) delivered at boiler .....$	8.75
23	Cost of coal for evaporating 1000 lbs. of water, F. and A. 212 deg.....	49.16c

HOURLY QUANTITIES

Time—8 a.m. to 9 p.m.	
Wt. of coal as fired .....lbs.	2,000
Wt. of water fed to boiler .....lbs.	14,000
Average Steam Pressure Gauge .....lbs.	150
Average Feed Temp. .....F.	60
Average Super Heat	0
Average Draft Over Fire .....inches	3
Average Flue Gas Temp. .....F.	550
Average Co2 per cent. .....p.c.	10
Per cent. Moisture In Steam	3

The test should be conducted for at least eight hours (the longer the better), and the hourly readings averaged up. The temperatures and pressures should be read frequently so as to obtain fair averages, and every few tubs or barrows of coal there should be a small amount of coal thrown into a box so as to get a fair average sample. The same is true of the ash and cleanings.

The main thing to remember is that we want to evaporate as much water as we can per lb. of coal fired. Note the style of firing, the frequency of coaling, and slicing, clinkering, cleaning, etc., for future reference.

The engineer who is conducting the test should have no part in the work except supervision. He should be free to go around from point to point making observations and above all have dependable persons as water tenders, at the measuring barrels. At the conclusion of the test the coal set aside for the sample is spread out on a clean part of the floor and broken up until it is quite small, not necessarily powdered, then it is quartered, that is divided in four sectors, throwing two sectors out each time until there is about a peck left. Box this up in a box sufficiently large that the coal when spread in the bottom will not be more than 2 in. deep, and place on top of boiler in a pretty warm place where some of the moisture will be dried out. (If the sample is quite dry, this will not be necessary, but frequently the coal is out in the weather and may be wet.) Before placing the sample away for drying weigh it and when taken down weigh it again. For instance if the sample put away weighed 20 lbs. and next day weighed 19 lbs.

$$\text{there would have been } \frac{(20 - 19) \times 100}{20} =$$

5 per cent. dried out. But this is not all the moisture. When the sample goes to the chemist he will find from 1 1-2 to 3 per cent. of moisture and this must be added to what has been dried out.

When we send the sample out for analysis before closing the box we will put a card inside giving the particulars we wish the chemist to analyze for. The following information is usually sufficient.

Required approx. analysis of enclosed sample of coal from plant of J. Jones & Company.

Shipment No.
Car Number.
Evaporation Test No.
Date of Evap. Test
Moisture.
Volatile matter.
Fixed carbon.
Ash
Sulphur, etc.

Treat the ash sample the same way except that the particulars required of the chemist are, the per cent. of combustible in the sample, giving the date of test, number of test, etc., so that we won't have the analysis sheet mixed up with some future test.

In the meantime while waiting for the results of the analysis, we may work up some of the test data to get a general idea of what the results were.

It is not always convenient to send out a sample for an analysis, and not always "absolutely necessary" since the purchasing dept. should have an analysis from the coal company supplying the coal, and this analysis should be available but its value is always more or less open to question.

We will now assume that the analysis has been made, and proceed to work up the test.

Let us say that the analysis of the coal sample is as follows:

Approx. Analysis

Moisture 2% + (5%) = (7% in coal as fire).
Volatile matter = 21.65%.
Fixed carbon = 47.80%.
Sulphur = 6.40%.
Ash = 18.00%.

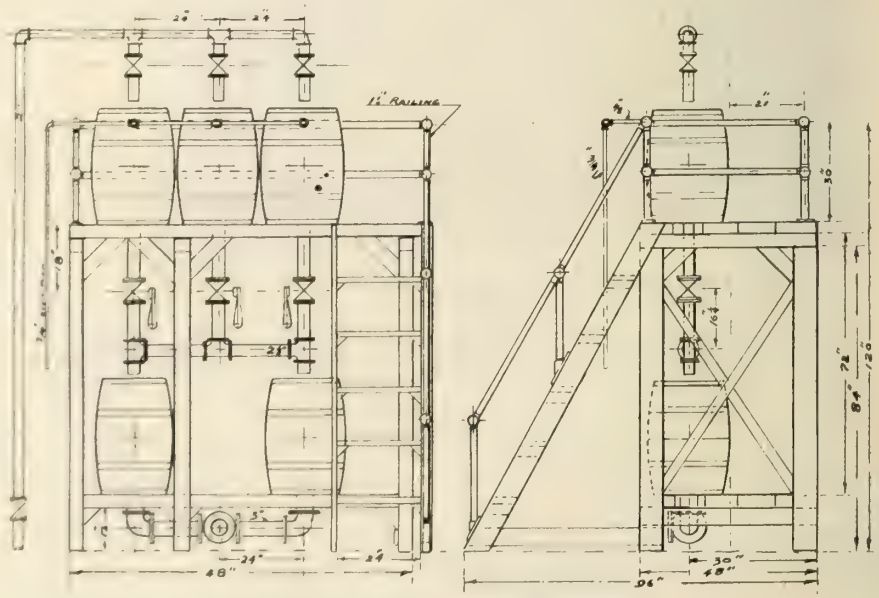
If we dried out 5 per cent. of moisture before sending the sample out we must add this to the 2 per cent. in the analysis report. Now the next thing to do is to find the heat value of the coal. Proceed thus. Find the percentage of combustible. The combustible is the volatile matter plus the fixed carbon. The sulphur is a combustible part, but in practice its heat value is so offset by other considerations that it is entirely ignored as a rule (a thorough explanation will take up too much space here) so we find by reference to the analysis report that the combustible is (21.65 + 47.8) = 69.45 per cent., by reference to the chart Fig. 4 and following the instructions we find that the heat value is 15,500 B.T.U. per lb. of combustible, and since a pound of the coal as fired contains only 69.45% of combustible

$$\text{the heat value is } \frac{(15500 \times 69.45)}{100} = 10765$$

B.T.U. per lb. as fired.

Let us now prepare a form in accordance with the A.S.M.E. Code.

Items 1 to 9 require no explanation, beginning with item 10. Dry coal per



Figs. 1 and 2.—Water measuring arrangement.

Data and Results of Evaporation Test

1. Test of ..... boiler located at .....
2. Number and kind of boilers .....
3. Kind of furnace .....
4. Grate surface (width.....length.....) ..... sq. ft.
5. Water heating surface ..... sq. ft.
6. Superheating surface ..... sq. ft.
7. Total heating surface ..... sq. ft.
   e. Distance from center of grate to nearest heating surface ..... ft.

Date, Duration, etc.

8. Date .....
9. Duration ..... hrs.
10. Kind and size of coal .....

Average Pressures, Temperatures, etc.

11. Steam pressure by gage .....lbs per sq. in
12. Temperature of steam, if superheated .....degs.
13. Temperature of feed-water entering boiler .....degs.
14. Temperature of escaping gases leaving boiler .....degs.
15. Force of draft between damper and boiler .....ins.
    c. Draft in furnace .....ins.
    d. Draft or blast in ash-pit .....ins.
16. State of weather .....
    a. Temperature of external air .....degs.
    b. Temperature of air entering ash-pit .....degs.
    c. Relative humidity of air entering ash-pit .....degs.

Quality of Steam

17. Percentage of moisture in steam or degrees of superheating .....% or degs.
18. Factor of correction for quality of steam .....% or degs.

Total Quantities

19. Total weight of coal as fired ..... lbs.
20. Percentage of moisture in coal as fired ..... per cent.
21. Total weight of dry coal fired ..... lbs.

hour = weight of coal fired per hour less the moisture, in this case 7 per cent. then multiplying the weight (sample tally sheet) $\frac{2000 \times 73}{100} = 1860$ lbs. (Enter this).

$$\text{Item 11} = \frac{1860}{84} = 22.14 \text{ lbs.}$$

Item 12 = (Actual water fed x Factor of evaporation). Here we must calculate the factor of evaporation, but before going any further we will have an explanation of what the factor means, and why it is used. In order that there would be some basis to compare the performance of steam boilers under different conditions of operation a rule was adopted by the A.S.M.E. and other engineering associations in convention, that a boiler H.P. shall be the evaporation of 34 1-2 lbs. of water at a temperature of 212 deg. Fah., into steam at the same temperature (which is simply evaporating water into steam at the atmospheric pressure).

If at one plant the boilers are generating steam at say 100 lbs. gauge from cold feed water and at another plant they generate at 150 lbs. gauge from hot feed water, their relative performance cannot be compared by the amount of water each evaporates, since the boiler using hot feed water will evaporate more than the one using cold water, this stands to reason.

Again, if one generates steam from cold water to a pressure of 100 lbs., and the other generates from the same temperature to a pressure of 150 lbs., they cannot be compared by the amount of water each evaporates, since the steam pressure is different.

It requires almost exactly 970.4 B.T.U. to change a pound of water at 212 deg. into steam at the same temperature. This is known as the Latent heat of steam at atmospheric pressure. Some steam tables now in use give the Latent heat of steam at atmospheric pressure as 958.6 and 966 B.T.U., but the latest accepted figures are 970.4 (make a note of this).

The formula for finding the factor of evaporation is

$$F = \frac{(H - t) + 32}{970.4}$$

in which H = total heat units in a lb. of steam at the given pressure (above 32°).
in which t = the temp. of the feed water.
in which F = the factor of evaporation.

The reason (32) is added to the numerator is because the tabled quantities (H) and (q) are above 32 deg. Fah. (the freezing point of water), while the feed water temperature is read in deg. Fahr. above zero. If 32 was subtracted from the feed water temperature then the formula would be $F = \frac{(H - t)}{970.4}$. In some of the text books we will find the formula written thus:

$$F = \frac{(L + q - t) + 32}{970.4}$$

which is exactly the same thing, since the column H is the sum of (L + q). Therefore (L + q) = H and $F = \frac{(L + q - t) + 32}{970.4} = \frac{(H - t) + 32}{970.4}$

Note that one boiler horse power is the equivalent of $\frac{(970.4 \times 34\frac{1}{2})}{60} =$ 557.98 B.T.U. per minute, equal to $\frac{557.98 \times 778}{33000} = 13.16$ mechanical horse power, so that the boiler horse power has no reference to engine horse power.

Now proceeding with Item 12, Eq. Evap. = (14000 x F) =

$$\frac{14000\ [(H - t) + 32]}{970.4}$$

and from the steam table (H, corresponding to the pressure of steam (150 gauge) = 1195 and substituting we have eq. Evap. =

$$\frac{14000 \times [(1195 - 60) + 32]}{970.4} =$$

$$\frac{14000 \times 1167}{970.4} = 16{,}836 \text{ lbs. (less 3 per cent.)}$$

(This should have been taken care of when calculating the factor of evap. See "quality of steam," etc.) Evap. =

$$\text{Item 13} = \frac{\text{Item 12}}{\text{Item 2}} = \frac{16531}{5000} = 3.367 \text{ lbs.}$$

Item 14 = The commercial H. P. x 34½ = (500 x 34½) = 17,250 lbs.

$$\text{Item 15} = \frac{\text{Item 12} \times 100}{\text{Item 14}} = \frac{16331 \times 100}{17250} = 94.7\%$$

$$\text{Item 16} = \frac{\text{Item 12}}{\text{Item 10}} = \frac{16531}{1860} = 8.9 \text{ lbs.}$$

$$\text{Item 17} = \frac{\text{Item 12}}{\text{lbs. Combustible}} = \frac{16331}{\left(\frac{1860 \times 69\ .45}{100}\right)} =$$

$$\frac{16331}{1291.8} = 12.64 \text{ lbs.}$$

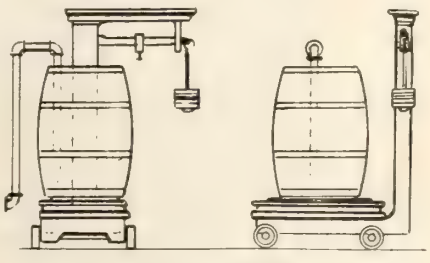


Fig. 3—Water measuring arrangement.

Item 18 = Value found by reference to chart = 10,765 B.T.U.

Item 19 = Ditto.

Item 20 =

$$\frac{\text{(Heat absorbed by the boiler x 100)}}{\text{Heat supplied in the coal}}$$

$$\frac{\text{(970.4 x Item 16 x 100)}}{\text{Item 18}} =$$

$$\frac{970.4 \times 8.9 \times 100}{10765} = 80.2\%$$

Item 21 =

$$\frac{970.4 \times \text{Item 17} \times 100}{\text{Item 19}} = \frac{970.4 \times 12.64}{15500} =$$

79.13 per cent.

Item 23 =

$$\frac{\text{(Item 22 x 1000)}}{\text{(Item 16 x 2000)}} = \frac{(8.75 \times 1000)}{(8.9 \times 2000)} = \frac{8.75}{17.8}$$

= .4916 dollars = 49.16c.

What the Test Shows

There is nothing to it, is there? "Well, not yet, anyway." The kink is to know whether the test is satisfactory or not, and if not just where the trouble is.

Let us assume that the efficiency of the boiler furnace and grate were found after an evaporation test to be 50 per cent., while the developed rating was only 95 per cent. There is something wrong here. We will find that the boiler heating surfaces are dirty or maybe that the firing was careless, allowing excess air through holes in the fire, or through leaks in the setting and fronts, carrying away too much heat to the chimney. The temperature of the flue gas is some indication of excess air and also of dirty heating surfaces, but no an infallible one, since the flue gas may be cooled off by the admission of air around the uptake. Again the flue gas may be hotter than it should be, but instead of dirty heating surfaces might be due to broken baffles allowing short circulating to the hot gases. This is where our draft gauge tells us something worth while. The readings should be taken at the uptake and in the first and second pass, as well as over the fire.

The flue gas temperature will be low according as the heating surface of the boiler is efficient, and vice versa. When there is no economizer in the uptake or path of the hot gases, the flue gas temperature should not exceed 500 deg. Fah. to 600 deg. Fah., depending upon how hard the boiler is being forced. When there is a superheater in the boiler the flue gas temperature is lower than if there is none because the superheater absorbs some heat, an ideal flue gas temperature would be pretty close to the steam temperature, but this is not possible of attainment in practice.

An analysis of the flue gas temperature may also be misleading if there are air leaks around the last pass, since the flue gas analysis is mainly to determine the completeness of combustion by analysis of the products thereof, it is important to be reasonably certain that the gases that are being analyzed are not mixed with air that leaks into the gas path between the furnace and the last pass, or point where the sample is taken. The presence of leaks in the uptake have no further effect on combustion than to reduce the power of the chimney to draw. That is combustion might be all that could be desired yet an analysis might indicate a great deal of excess air, due to infiltration through the setting beyond the combustion space. On the other hand the analysis might indicate good furnace conditions, while the reverse might be the truth, due to insufficient draft, or furnace volume combined with leaks in the setting. However to the experienced man, or one who studies the subject a little, there is usually no difficulty in running down any troubles to their source.

In average every-day practice it is not usual to analyze for carbon monoxide (CO) but the greatest importance is attached to amount of carbon dioxide (CO_2) present in the flue gas. A thorough instruction in "Flue gas analysis" has no place here and it is sufficient to state that if the average CO_2 is 12 per cent., the furnace conditions are as good as general every-day practice will admit. When the CO_2 is below 8 per cent. there is something radically wrong and it is invariably caused by excess air through rat holes in the fire.

There is a falling off in efficiency at high ratings due to forcing the fires, in order to get high capacities. This falling off is principally due to the high velocity of the gases through the boiler, preventing heat absorption by the heating surfaces and a consequent loss of heat up the chimney.

The chart Fig. 6 showing the draft loss between the damper and the furnace may be taken as some guide to the condition of the baffles in a vertically baffled boiler. The loss in a breaching is 0.001 inches per foot with 0.05 inches loss for every right angle turn and about 0.4 inches through the boiler.

As an example, assume the chimney to be 175 ft. high and the breeching 40 ft. long, one right angle turn at the entry to chimney and one at boiler uptake. Estimating $\frac{4}{10}$ loss through the boiler, what draft should be expected over the fire when the flue gas temperature is 500 deg. Fah. and the outside temperature 60 deg. Fah.

Theoretical chimney draft $D =$

$$H\left(\frac{7.64}{T_a} - \frac{7.95}{T_c}\right)$$

in which D = Draft in inches of water.

in which H = Height in feet above grate.

in which T_a = Absolute temperature of the outside air.

in which T_c = Absolute temperature of the flue gas.

The draft at the stack—

$$D = 175\left(\frac{7.64}{(60 + 461)} = \frac{7.95}{(500 + 461)}\right)$$

$$= \left(\frac{7.64}{521} - \frac{7.95}{961}\right) \times 175 =$$

175 (0.014683) — (0.008272) = 1.12 inches of water.

The actual draft will be about 80 per cent. of this. Therefore the measurement at the stack should read $\frac{(1.12 \times 80)}{100}$ = 0.896 inches.

Loss through the breaching = (140 x 0.001) + (0.05 x 2) = (0.04 + 0.1) = 0.14 inches.

Draft over the fire should read 0.896 — (0.14 + 0.4) = 0.356 inches.

In actual practice the draft gauge would read a little lower since some

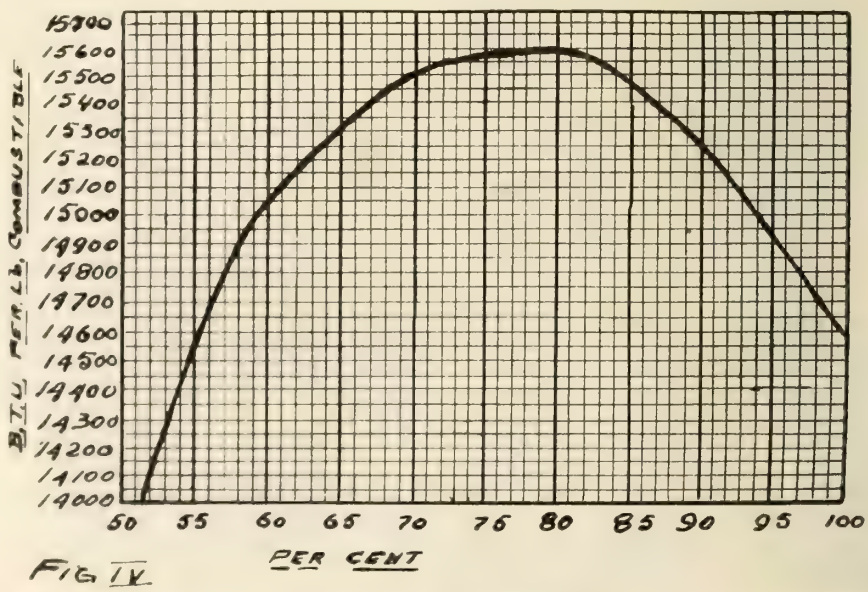

Fig. 4.—Chart for finding heat value per lb. of combustible. Correct to 3 per cent. when combustible in fuel is between 64 and 72 per cent.

slight allowances must be made, but should not read less than 0.3 or $\frac{3}{10}$ in. and certainly not more than $\frac{35}{100}$ when the fire is clean and burning free. A stronger draft over the fire would indicate short circuiting across the baffles (unless the fire is clinkered over) or would indicate very high flue gas temperature.

Quality of Steam

The quality of the steam is an important factor in a test report since it may be that a considerable amount of the water fed to the boiler may be carried away in the form of moisture in the steam, and credited to the boiler as being evaporated. There are three methods of finding the moisture content of a sample of steam. The one most common is by throttling calorimeter determination described in Fig. 8 which will give accurate results when the moisture content in the steam is not over four per cent. The separating calorimeter is probably the most reliable and will give accurate results even when there is considerable moisture present in the steam. The barrel calorimeter is sometimes used but it is not at all a reliable means and only the first will be described. When the amount of moisture in the steam is known, the quality of the steam is expressed as a percentage of its dryness. Example, a test shows 3 per cent. of moisture present, then quality of the steam is 93 per cent. and from this the factor of evaporation becomes

$$F = \frac{(xL + q - t) + 32}{970.4}$$

in which x = the quality of the steam expressed as a decimal.
in which F = Factor of evaporation.
in which L = Latent heat at observed pressure
in which q= heat of the liquid.
in which t = Feed water temperature.

Example—Quality of the steam is 93 per cent. = (0.93) observed pressure of the steam 150 lbs. gauge, feed temp. = 60 deg. F. Find the factor of evaporation.

Referring to the table of properties of saturated steam we find

$$L = 856.4 \qquad q = 337.7$$

$$\text{Then } F = \frac{(xL + q - t) + 32}{970.4} =$$

$$\frac{(0.93 \times 856.4) + 337.7 - 60) + 32}{970.4} =$$

$$\frac{1106.152}{970.4} = 1.14$$

When the steam is superheated it is usual to refer to an especially prepared chart if the greatest precision is required. But since the chart is prepared on the basis of the amount of heat absorbed by the steam per lb. the following formula will be sufficiently accurate for average purposes.

$$F = \frac{(H - t) + 32}{(S)} \text{ in which } S = 9704 + \frac{}{(2)}$$

the number of deg. of superheat.

That is it requires approximately ½ a B.T.U. to raise the temperature of 1 lb. of steam one deg. Fah. The specific heat of the steam varies with the pressure and averages 0.5 for moderate pressures. If it is desired to know definitely the exact factor for superheated steam it can be found as follows:

$$F = \frac{(XL + q - t) + 32}{(970.4 + Sc)} \text{ in}$$

which C = specific heat of steam at the observed pressure.

Now a final word on a subject that has caused more arguments than any other in connection with evaporation tests.

If the injector is used to feed the boiler and the feed temperature is measured at the entry to the boiler the steam used by the injector will not have to be estimated. If on the other hand the feed temperature is taken as that at the injector barrel the steam used by the injector must be charged against the evaporation.

The steam used by the injector is condensed by the water and all the heat is returned to the boiler except the small amount of radiation from the pipe and injector itself. Don't forget that the water the injector slops over at the overflow is measured water and must be accounted for. If it is at all possible the temperature of the feed entering the boiler should be known. The main thing to know on a test of this kind is the evaporation, unless the test is an overall one, it does not matter where the steam goes, whether to the engine, injector or pump. We are mainly concerned with evaporation (F and A) 212 deg.

First Method

Assume a pressure of 150 lbs. gauge and let the temperature of the water at the suction be 60 deg. Fah., and at the discharge 170 deg. Fah. Let the amount of water fed be 14,000 lbs. per hour, the heat units given up to the water are:

W (T — t) in which T = discharge temperature.

In which t = the suction temperature.

In which W = weight of water fed per hour.

Then Q = lbs. steam supplied to the injector.

L = Latent heat of steam at observed pressure.

$$14{,}000\ (T - t) = 14{,}000\ (170 - 60) = 1{,}540{,}000 \text{ B.T.U.}$$

Now all the heat units in the steam supplied at the observed pressure (150

Amount of Steam Used by the Injector

If the temperature of the water leaving the injector is known and the temperature at the suction is known, there are two simple methods by which we can find out the quantity of steam used, assuming it to be dry saturated steam.

lbs. gauge) above the temperature of the discharge (170 deg.) are represented by 1,540,000 B.T.U. and let us call the steam temperature at the given pressure of 150 lbs. gauge (Z). The lbs. of steam supplied to the injector can now be found.

$$\therefore Q = \frac{W\ (T - t)}{L + (Z - T)} = \frac{14{,}000\ (170 - 60)}{856 + (366 - 170)}$$

$$= \frac{14{,}000 \times 110}{1052} = 1{,}464 \text{ lbs. per hour.}$$

This can be proven by the formula used to find the final temperature of a mixture of steam and water.

$$\text{Thus } T = \frac{Q\ (L + Z) + (Wt)}{Q + W}$$

In which T = the final temperature of the mixture.
In which t = the temperature of the water.
In which Z = the temperature of the steam.
In which L = the Latent heat of the steam.
In which Q = the weight of the steam (lbs.)
In which W = the weight of the water (lbs.)

Substituting—

$$T = \frac{1464\ (856 + 366) + (14{,}000 \times 60)}{14{,}000 + 1464}$$

$$= \frac{(1464 \times 1222) + 840000}{14000 + 1464} = \frac{2629000}{15464}$$

= 170 deg. F.

The other method is by a slightly more difficult formula as follows:

$$Q = \frac{W\ [(T - t)\ D + 0.1851P]}{[H - (T - 32)]\ D - .1851P}$$

In which P = the absolute pressure of the steam.
In which D = the density of the water at the disch. temp. (or the wt. of water per cu. ft. at the dischg. temp.).
In which H = the total heat of the steam above 32 deg.

The other symbols as above.

Example—Assuming the same conditions as before (and taking the density of the feed water at 170 deg. = 60 lbs. per cu. ft.). Then

$$Q = \frac{14000\ [(170 - 60) + 0.1851 \times 165]}{[1199 - (170\text{-}32)]\ 62 - 0.1851 \times 165}$$

$$Q = \frac{14000\ (6600 + 30.5415)}{(1194 - 138)\ 60 - 30.5415}$$

$$\frac{14000 \times 6630.5415}{(1056 \times 60) - 30.5415}$$

$$Q = \frac{92827000}{63329.5} = 1462.5 \text{ lbs. per hour,}$$

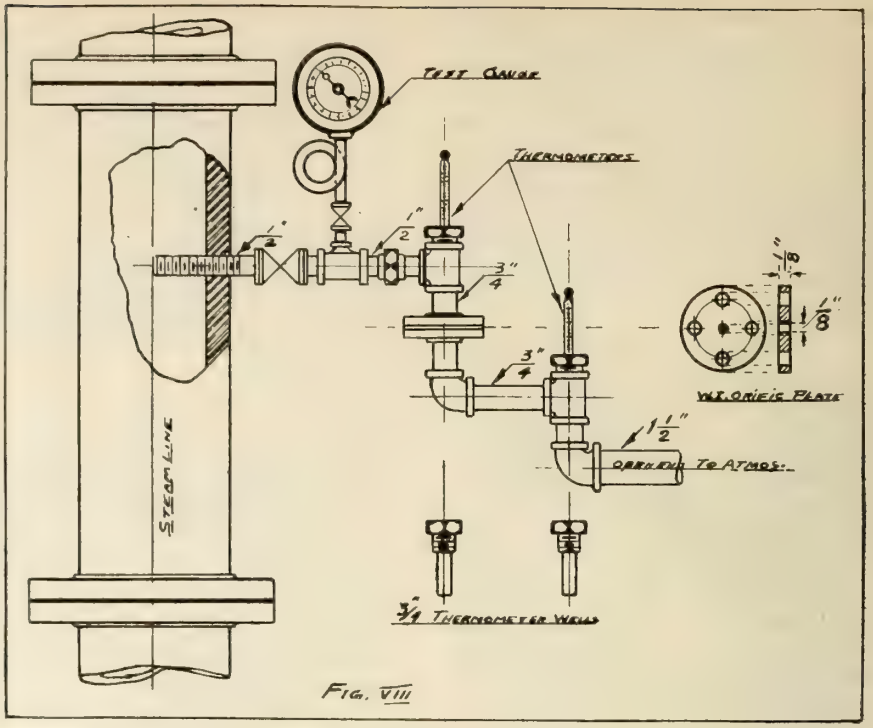

Fig. 8.—Throttling Calorimeter.

or a difference of 1½ lbs. for the last method which is the correct one, but much more cumbersome.

Fig. 8 illustrates a throttling calorimeter that can be made by anyone. The only point is that two excellent authorities disagree about two of the features.

One authority advises that the ½ in. pipe inserted in the steam line should be perforated with 1-8 in. holes and that they should not be within ½ in. of the walls of the steam line and that the orifice in the plate should be 1-16 in.

While the other advises that there should be no perforations and states that the orifice should be 1-8 in. diameter and the end of the tube midway in the stream.

The upper thermometer is used to check the steam pressure gauge, there should be perfect agreement between them. The lower thermometer reading is used to find the quality (x) of the steam.

To estimate the quality of the steam we have the following formula:

$$x = \frac{(H - q) + 0.46\ (T - t)}{L} \text{ in which}$$

x = quality of steam expressed as a decimal.
H = Total heat of dry steam (saturated) at atmospheric pressure — (1150.4).
q = Heat of the liquid corresponding with the boiler pressure (B.T.U. per lb.).
T = The temperature shown by the lower thermometer.
t = The temperature of saturated steam at atmospheric pressure = (212 deg. F. when the atmospheric pressure is 14.7).
L = the latent heat of steam at the boiler pressure 0.46 = the specific heat of superheated steam at atmospheric pressure.

Example—Assume that the boiler pressure is 150 lbs. gauge and the upper thermometer reads 366 deg. F. the lower 250 deg. Estimate the quality of the steam

$$x = \frac{(H - q) + 0.46\ (T - t)}{L} =$$

$$\frac{(1150.4 - 338.2 + 0.46(250 - 212)}{8.56.8}$$

$$= \frac{812.2 + 2208}{856{,}8} = \frac{834.28}{856.8} = 0.9737 \text{ or}$$

97.37 per cent. dry steam, or in other words the test shows that the steam contains 2.63 per cent. moisture.

A few remarks about the value of an evaporation test to determine the advantage of using one grade of coal as compared with another, then I will leave the reader by himself to go to it and test to his heart's content. I know that he won't for the consideration of two or three old oil casks and a few fittings be content to set back and let dollars and dollars flow out the chimney, and to further interest him I will give him an actual instance which came to the writer's notice, the thing was actually done by very common fellows, under the direction of an excellent engineer, who is a Canadian and a graduate of a Canadian college.

But the thing was so simple when demonstrated that it was amazing even to some of us who thought we knew a lot.

A certain plant was evaporating an average of 5,000,000 lbs. of water per week. The cost of evaporation was found to be 52 cents per thousand lbs. (coal

prices were sky high at the time, and are yet for that matter).

$$\text{Cost of evap. per week} \frac{(5000000)}{1000} \times \frac{52}{100}$$

= $2600 per week.

By a series of evaporation tests and making use of the information thus gained to bring up the efficiency of operation, and demonstrating the proper kind of fuel to use, and how to use it, the cost of evaporation was reduced to 26 cents per thousand lbs., a saving of $1300 per week. (The cost referred to is evaporation cost not production cost) at the expense of a little extra time and equipment picked up on the plant. This is not a fairy tale but an actual fact. Well, was it worth while? I'll say it was.

Fuel is or should be purchased on a heat unit basis. That is on a basis of B.T.U. per dollar but it does not follow that the highest grade coal is the most profitable in all cases, and the only way to demonstrate is by an evaporation test under actual working conditions.

Boiler furnace and grate efficiency is one thing, cost of evaporation is another, and capacity is still another. So by a series of evaporation tests, carefully conducted, with the most meagre equipment we will find out that a great deal of what we had taken for granted is not so, and when we have closed up the open "bung hole" in the boiler room, we will proceed to the engine room to see whether there is a leak at the spigot.

Application of the Chart Fig. Four

To estimate the heat value of a coal with a given approximate analysis, add together the percentage of fixed carbon and the percentage of volatile matter in the coal, divide this sum into the percentage of fixed carbon and multiply by 100. This gives the percentage of fixed carbon in the combustible or

$$\frac{\text{(Fix. Car.) } 100}{\text{Fix Car + Vol.}}$$

= percentage of fixed carbon in combustible.

Locate this percentage at the foot of the chart, extend your pencil straight up until you strike the curve, then following the nearest horizontal line read the B.T.U. per lb. of combustible. Multiply the value thus found by the percentage of combustible in coal and the result will be the heat value of the coal per lb.

Example—If the volatile matter is 30 per cent., and fixed carbon is 45 per cent.; find the heat value.

$$\text{Then } \frac{45 \times 100}{45 + 20} = \frac{4500}{65} = 69.23$$ locating this point on the curve and following the horizontal line to the left we find the heat value per lb. of combustible = 15,500 B.T.U. and since the coal contains (45 + 20) = 65 per cent. combustible. The heat value is $\frac{15500 \times 65}{100}$

= 10,075 B.T.U. per lb.

VAPOR ACCUMULATORS

In the majority of industrial plants where steam i used, the steam consumption varies. This means that the fire under the boilers will have to be changed according to the variation in the steam consumption, which again means poor steam economy with the risk of either shortage of steam or a surplus, with the safety valve blowing.

Instead of giving their attention to the matter of obtaining the best possible combustion with a high CO-2 percentage, the firemen have to watch the pressure in the boilers, always to be ready to increase or decrease the steam flow.

If the firemen has fixed the load and the draft of the boilers for a good combustion, the next time he changes the rate, the CO-2 will drop or go too high, and thus it is impossible always to keep the combustion at the point where it should be.

It is also a common occurrence that one or two boilers are kept under fire in order to take care of the peaks in the load which can not be provided for from the boilers normally required

It is obvious that the economy of these "spare" boilers is exceedingly poor.

The above conditions which undoubtedly have been noticed by every boiler house superintendent, have been considered impossible to get away from, and, on account of the absence of any way to improve them, they have been considered unavoidable.

Lately, however, an invention called the "Vapor Accumulator" has come into use extensively in Europe and the results obtained with same have been very good.

The idea of the "Vapor Accumulator" is, to store the excess steam produced at times of low steam consumption, until periods of high steam demand, when it is again drawn off.

The accumulator, in other words, acts as a buffer between the steam producer and the steam consumer and the firemen have only to watch that the accumulator does not get empty or too full.

In this way, the boilers need only produce the average quantity required for the plant and the load of the boilers can be kept even and independent of the temporary steam requirements.

It is evident that only that number of boilers necessary for the production of the average steam quantity required need to be under fire, which means that the "spare" boilers can be entirely eliminated and often one or two more of the others.

The accumulator is equipped with complete automatic regulation worked by the pressure in the various steam lines. This gives a practically constant pressure to all steam consumers.

Beside the direct saving of fuel gained by the use of the accumulator the operation of the plant itself is simplified to a considerable extent.

The power house takes the place of an auxiliary equipment in the plant, which it ought to have, after the "Vapor Accumulator" has been installed, and not, as has heretofore very often been the case, the position of the most vital part of the plant, according to the condition of which every other department had to be operated.

In case of a sudden stop in the operation of a boiler, or cleaning, etc., the accumulator will step in, to a certain extent, so that no break in the steam supply will be noticed in the other departments of the plant.

In pulp and paper mills where it is of utmost importance to have an even and high quality of the product, it is very valuable to be able to keep the desired pressure constant both in the digester houses, paper machines, drying machines, etc., at all times, even when, for one reason or other, there should be disturbances in the boiler house.

NEW MINE RESCUE APPARATUS

Ever since the invention of the Miner's Safety Lamp by Humphry Davy, Great Britain has devoted keen attention to the subject of safety devices in mines. Experiments recently conducted by the British Scientific and Industrial Research Department have resulted in the design of two new types of rescue apparatus which are proving most successful. Both types of apparatus are what is known as "regenerative"; that is to say, the air expelled by the lungs is purified, supplied with oxygen, and returned to the lungs. Therefore, when a man wears this apparatus he is able to enter smoke or poisonous atmosphere without suffering ill effects. The apparatus and the lungs really form a closed circuit, and the lungs serve as a pump to circulate the air round that circuit. In one type of apparatus the oxygen is supplied from liquid air and in the other type it is obtained from a solution of compressed gas. Both pieces of apparatus are designed to enable the wearer to undertake continuous heavy physical exertion for at least two hours. As a matter of experience they can satisfy all the breathing needs of the wearer for three hours.

The largest Hydro Electric Plant at Chippawa was officially opened on Wednesday, December 28th. About 2,000 municipal representatives were present, and water was released into the first installed turbine setting in motion the 55,000 H. P. generator. At the present time only one turbine will be used but when the actual plant is completed there will be nine turbines in all which will have approximately a capacity of 650,000 H. P.

The Gas and Oil Engine In the Power Plant

The Internal Combustion Engine Is Becoming of More Importance to The Power Plant Field Daily. This Article, The First of a Series, Discusses The Leading Principles In a Plain Manner

By T. H. FENNER.

THE power plant engineer in Canada has been inclined to look on the internal combustion engine in its various forms as something which possessed but little interest for him. What attention he had given to this form of prime mover has been rather superficial as being something out of his immediate needs. The time has come however, when that attitude must be changed, for the internal combustion engine is now in active operation in a large number of places in Canada. The man who has confined his attention to steam entirely, may suddenly be called upon to attend to an engine which uses a different medium to produce its power, and every man should have at least a good general knowledge of the principles under which these motors work.

Internal Combustion

When we speak of the internal combustion engine, we mean any engine in which the working medium, or fuel, accomplishes the chemical combination with oxygen which we know as combustion, in the same chamber in which the power made available by combustion is used. That is the fuel is mixed with air necessary for its complete combustion, ignited, and develops its power while in direct contact with the piston which it is to drive.

In the steam engine on the other hand, the fuel is ignited and combustion completed, in a vessel absolutely distinct and apart from the engine which is to be utilised to develop the power of the fuel. The heat of combustion is transferred to the water in the boiler by radiation and conduction from the furnace and combustion chambers, and the result is the change of water into a gas, which carries part of the heat of combustion over to the engine cylinder, and there gives it up by doing work on the piston. The above short description shows the fundamental difference between the two types of engine, and it will need only very slight consideration to show wherein lies the superiority of the internal combustion engine from the point of view of heat efficiency.

Heat and Work

Any engine at all is a heat engine, and is merely the mechanism by which the foot pounds of work contained in the heat supplied may be converted into mechanical energy. Whatever the fuel we may use to give us this heat supply, it will contain a certain amount of energy in the form of heat units, it is the object of the engineer to transform these heat units into mechanical energy with the least possible loss taking place in the

One pound of ordinary coal contains about 11,000 B.T.U. and this expressed in foot pounds is 8,558,000. If the energy contained in the pound of coal could be developed over the period of one hour without any loss, then measuring in our usual terms for power, we should have 142,633 ft. lbs. per minute, or power at the rate of 4.3 horse power for one hour. That is, the energy contained in one pound of coal is sufficient if it could be applied without loss to develop 4.3 horse power hours.

Now what do we find in practice? The most efficient prime mover using steam as a working fluid develops one horse power hour for the consumption of one pound of coal. That is the pound of coal actually develops in the best apparatus that we have only a little less than one quarter the energy equivalent of the heat units it contains. Evidently here we are a very long way from our object of transforming the potential energy of the fuel into the mechanical energy we require without loss. With steam as the working medium, that is the medium which transmits the heat from the boiler to the piston of the engine and there allows it to do work, the above result is about as good as can be obtained. The use of oil as fuel instead of coal shows some improvement over this but still losses are enormous and to the steam engineer are only too familiar. A brief mention of them here will suffice. There is the loss caused by unburnt fuel dropping in the ashpit, the loss caused by the waste heat carried up the stack, losses by radiation from the boiler, steam pipes, etc., loss caused by condensation in the cylinder if the engine is a reciprocating one and the loss in the exhaust.

It is quite obvious that if we have a means of developing the heat units right where they are to perform their work, and have the heat energy developed directly in the working fluid, that we shall have eliminated a large amount of the sources of loss. This then is where the internal combustion engine obtains its great advantage.

In the Diesel oil engine one horse power is developed on a consumption per hour of about one half pound of fuel. If the fuel supplied to the engine contains 18,000 B.T.U. per lb., then we have 9,000 B. T. U. per hour. That is enough energy without loss to supply work at the rate of 3.5 h.p. or 3.5 horse power hours. Comparing this with our highly efficient turbine unit we find that in the oil engine we have obtained .2857 of the work actually available in the fuel, while in the steam turbine we have only obtained .2325. We have gained nearly 22 per cent. in the oil engine as compared with the fuel used in the steam turbine.

We have made this gain because the heat energy contained in the fuel has been applied to the machine which transforms it into mechanical energy in a much more direct manner. The unavoidable losses in the internal combustion engine are confined to the heat carried away in the circulating water, and the heat in the exhaust gases. The heat carried away in the circulating water would if not taken care of, result in the walls of the cylinder and the piston becoming red hot with disastrous results. The heat contained in the exhaust gases can be utilised if necessary in much the same manner that the exhaust steam from an engine can be utilised for heating purposes.

We have explained in a brief way where the internal combustion engine derives its great advantage over the steam engine, and while there will be no attempt in these articles to go into the thermo dynamics of the question, there is a simple means of showing in figures the great advantage of the internal combustion engine from a thermal point of view.

Heat Efficiency

In discussing questions relating to heat engines, it is usual to calculate from the absolute zero of temperature, instead of the ordinary thermometric reading. Many of our readers will be familiar with this method but for those who are not, it will be just as well to give a short explanation of what we mean by the absolute zero of temperature.

Absolute Zero

In investigating the effect of increases of temperature on the volume of air, it was found that every degree of temperature added on the Fahrenheit scale gave an additional volume of 1-460 part of the original. It necessarily followed that for every decrease of one degree a corresponding diminution of volume would occur, and if this was followed to its logical conclusion, there would be a point reached where there would be no volume, and accordingly no temperature. This point would occur at a temperature of 460 below zero Fahrenheit, and though such a temperature could not actually be attained, it formed a convenient base for a starting point. Therefore 460 below zero Fahrenheit is said to be the absolute zero of temperature Fahrenheit, the corresponding zero on the centigrade scale being 273 below zero.

The efficiency of a heat engine depends on the range of temperature of the working fluid in the cylinder, that is the greater the distance between the

initial and final temperatures, the greater the efficiency. This ideal theoretical efficiency is therefore expressed as follows:

$$\frac{\text{Heat put in—Heat rejected}}{\text{Heat put in}} \times 100$$

equals the efficiency expressed as a percentage. This is again expressed by the formula

$$\frac{T - t}{T} \times 100$$

where T is the absolute initial temperature and t the absolute final temperature.

This formula expresses the ideal efficiency, because in practice there are losses of heat from the radiation, etc., from the cylinder, which are not available for doing work. It forms however a convenient basis for showing the difference in efficiency between an engine using steam as a working medium, and one using a fuel which is burnt directly in the cylinder.

Thus if we take the example of our turbine, with an initial steam pressure of 150 lbs. per square inch, exhausting at 2 lbs. absolute we have the following values for the formula:

$$\frac{358.5 + 460 - 126.15 + 460}{818.5} \times 100$$

which is 28.1 per cent.

Now take an oil engine working between the temperatures of say 1,700 and 850, which would be 2,160 absolute and 1,310 absolute. By the formula

$$\frac{2160 - 1310}{2160} \times 100$$

is equal to 39 per cent.

Thus we see that the temperature range possible in an oil engine is far greater than that in a steam engine, and further the losses are far less if we consider the losses from furnace to exhaust in the steam engine.

The foregoing shows that the internal combustion engine considered as a heat engine is considerably in advance of the steam engine, but it must not be supposed that for every purpose the internal combustion engine can supplant the steam engine. The choice between the two prime movers would be influenced in many cases by local conditions, such as price and availability of coal, or oil, nature of the work to be done, investment costs, etc. Thus in a factory where large amounts of steam had to be used for process work, and for factory heating in the winter, a steam plant would very likely be the better proposition. On the other hand, in many localities where coal is both poor in quality and dear in price, and the power is required for generating electricity, the internal combustion engine could show many advantages.

A special field for the internal combustion engine has developed in the case of municipal water works where the water is pumped by means of centrifugal pumps direct connected to motors operated by electric power. There is a necessity in these cases for a standby unit, which can be always ready to start in case of failure of the electric power. Formerly it was the practice to put in a steam plant for this purpose, and naturally the charges involved were heavy due to the necessity of constant attention, and the cost of keeping fires banked, as well as a reserve of coal which had to be kept on hand.

The introduction of internal combustion engines to these plants gave a unit which was always ready to be put in commission at a moment's notice, which involved no standby costs, a very small investment in fuel, and no attention when not in use. We shall give some particulars of these installations in a future article.

Different Types of Engine

The term internal combustion engine covers a wide variety of motor, and they can be divided into types, according to the fuel used, and the cycle employed.

Thus there are the gas engines, which use as fuel, gas furnished by gas producers, town gas, or waste gases from blast furnaces, etc.

The engines using the lighter distillates such as coal oil, gasoline, benzine, etc., and adapted to the use of automobiles, areoplanes, etc., and small motors for concrete mixers, threshing machines and small lines of shafting.

There are the engines using the heavy oils, such as crude oil, and known as Diesel or semi-Diesel engines.

In the gas and gasoline engines, the charge is ignited by means of a spark produced from a battery or magneto. In the semi-Diesel engines ignition is produced by means of a portion of the cylinder cover which is uncooled, and thus attains a temperature which keeps it red hot, this heat serving to ignite the fuel charge when introduced. When starting the engine it is necessary to heat this portion of the cover, which is known as the hot-bulb, by some external means. There are various devices for this purpose. From the method of ignition this type of engine is often referred to as a hot-bulb engine.

The full Diesel engine differs from all the others in that the necessary heat for explosion of the charge is produced by the compression of the air in the cylinder, by the piston of the engine. This compression is high enough to produce a temperature in the cylinder of about 1000 degrees before the charge is admitted. The high temperature ensures instant ignition of the charge, and combustion is almost perfect. Owing to the high compression used, a very high range of temperature is secured, and these conditions make the Diesel engine the most efficient heat engine that we so far have developed.

(To be continued)

DON'T FORCE A BELT TO RUN ON THE PULLEYS

"Many millwrights make the mistake of thinking that it is perfectly proper to force a belt to stay on its pulley by any means whatever." "They seem to think, continues a writer in 'Belts,' "that as long as the belt 'runs' it is all right, and is doing as much as should be expected of it." For instance, one millwright "took a piece of old three-inch rubber belt, pulled off one ply, wrapped it twice around the centre of a wooden pulley and nailed it solidly to the pulley," and then he goes on and says, "The belt immediately took its place in the centre of the pulley and stayed there."

It is true that nailing a ridge of any kind of belting on a wooden pulley to increase the crown will cause the belt to move over and run on the intensified crown, even though the alignment of the pulleys may be poor. However, such a condition is hard on the belt, as a little thought would show that if the belt has much work to do it cannot endure.

Let us say that the width of the belt is 6 inches, and that the width of the ridge nailed on the pulley is only 3 inches. 6 inches minus 3 inches equals 3 inches, which means that about 3 inches of the belt (1½ inches on each side of the centre) is not in contact with the driving pulley or driven pulley at all or is in poor contact. A very intense pressure between the belt and the pulley occurs over the 3 inches of width of the ridge. In other words, 3 inches of width of belt is compelled to do what 6 inches was intended to do.

Furthermore, with the rough face of the ridge rubbing against the equally rough face of the belt, and with the pull per square inch and the pressure per square inch doubled, it is evident that the wear on the 3-inch ridge is going to be greater than it would be on a smooth iron or smooth wooden pulley. It is quite possible that the slip is greater with the 3-inch strip than without the strip. At least the creep is as great one way as the other. From every angle, therefore, it is obvious that nailing a ridge around pulleys to increase the crown is poor engineering.

It is far better to carefully align the pulleys and shafting so that the belt will run exactly as was intended by the designers of the pulleys. By using the low crown, the entire belt surface comes in contact with the pulley, both the load and the wear are evenly distributed. In fact, pulley coverings should not be used at all. It has been proved time and again that the natural smooth face of a metal, wooden or other pulley is far superior to any roughened face. Rough faces are too hard on the belt.

Plumbing and heating contracts for additions to hospital costing $107,986 for the Royal Jubilee hospital, Victoria, B. C., have been awarded.

Burning Wood Refuse in Mechanical Stokers

The Successful Combustion of Wood and Other Factory Refuse Has Always Been an Interesting Question—This Article Describes Various Types of Boilers Fitted With Underfeed Stokers For This Purpose

By R. L. BEERS*

UNTIL RECENT years many plant engineers considered the burning of wood refuse more from the standpoint of an easy method of disposal rather than a source of fuel supply. The high cost of coal, however, and the difficulty of securing it has caused considerable inquiry as to the proper methods to be used in burning wood refuse of various sorts so that the utmost heat value could be obtained.

There are such wide differences in the heat and moisture content that special furnaces are necessary for each kind of refuse to be burned. Where the moisture content approximates 70 per cent., burning the refuse becomes simply a matter of disposal—as the heat content is all required to evaporate the moisture.

There are three general classes of wood refuse that have been burned extensively on underfeed stokers. These are hog-feed, tan bark and sawdust.

Burning "Hog Feed"

"Hog Feed" is the most important of these three and is available in a number of plants in large quantities. "Hog Feed" is refuse wood obtained from pulp, paper and sawmills and consists of chips, blocks, etc., that have been put through a hogging machine or macerator. These machines, with the action of revolving knives, cut or shred the wood into a condition in which it can readily be handled as fuel. Mill refuse fuel is available at most of the pulp and paper plants and in lumbering sections. It is quite an important fuel on the Pacific Coast where there is a surplus of the material and it is sold to plants for steam purposes. The fuel usually contains a high percentage of moisture, varying from 40 to 75 per cent and it is essential in burning it that a large combustion space be supplied. On account of the high moisture contained there should be much heated brick work to radiate the heat to the fuel bed and thus assist in evaporating the moisture. Dutch ovens or extension furnaces of the proper size are usually essential for good results.

A common practice in burning this fuel has been to use natural draft and ordinary grates. The best results, when burning on grates, have been obtained by using a Dutch oven or extension furnace and dropping the refuse through an opening in the top of oven. This has been the common practice. However, with natural draft, the efficiency in burning the fuel is not very high. It is necessary to keep feeding a large volume of the fuel which requires constant opening and closing of the feed hole in the top of the Dutch oven. The feed hole is often left open permanently. This admits to the furnace a large volume of excess air that cools off the gases and makes it difficult to generate the maximum possible amount of steam. Better results have been obtained by using forced draft under the grates. This permits carrying practically a balanced draft over the fire and there is not so much excess air drawn in through the feed hole.

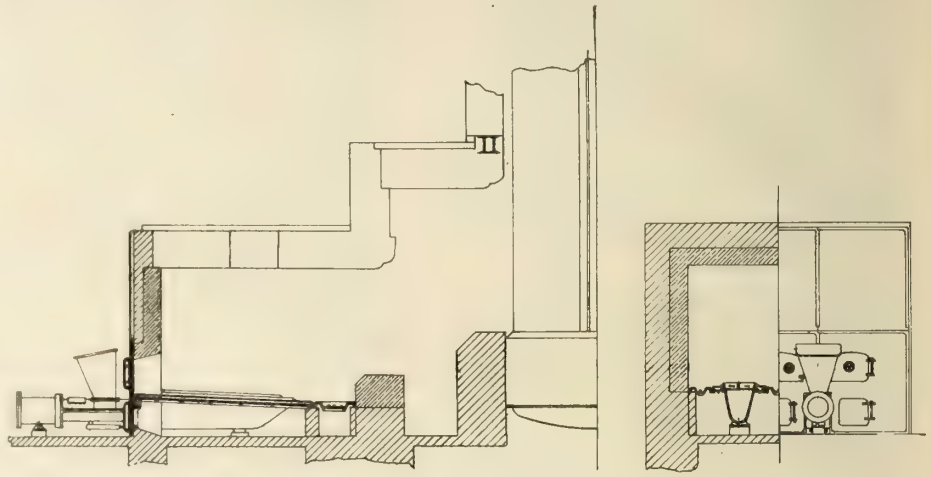

Fig. 2.—Wet wood furnace and stoker.

A standard type of under-feed stoker with stationary dead plates for hand cleaning has been extensively used for burning this fuel. The stoker offers a decided advantage over the forced draft grate fire as it is possible to have a fire both at the bottom of the pile of refuse as well as at the top of the pile. With the ordinary grate firing the fire is practically at the surface as the hot brick work radiates heat to the conical refuse pile, drying it out and igniting it. With the stoker a small amount of coal is fed through the retort which maintains a fire at the bottom of the fuel bed. This is essential in burning refuse with a high moisture content. The feed opening for the refuse is usually directly over the retort and the thin part

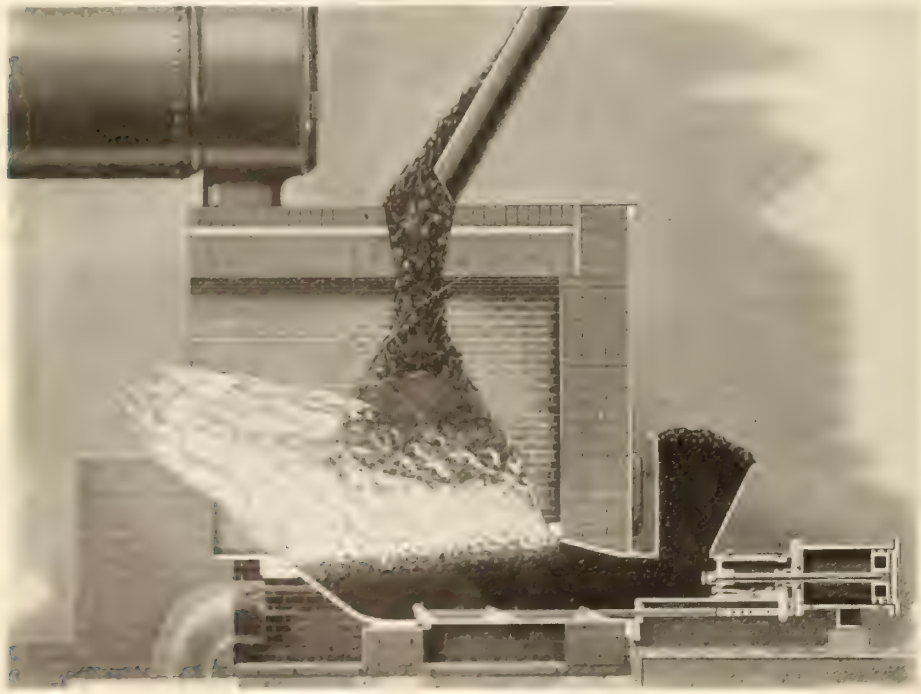

Fig. 1.—Hand-cleaned type stoker for burning hog fuel.

*By R. L. Beers, Assistant Chief Engineer, Underfeed Stoker Co. of America.

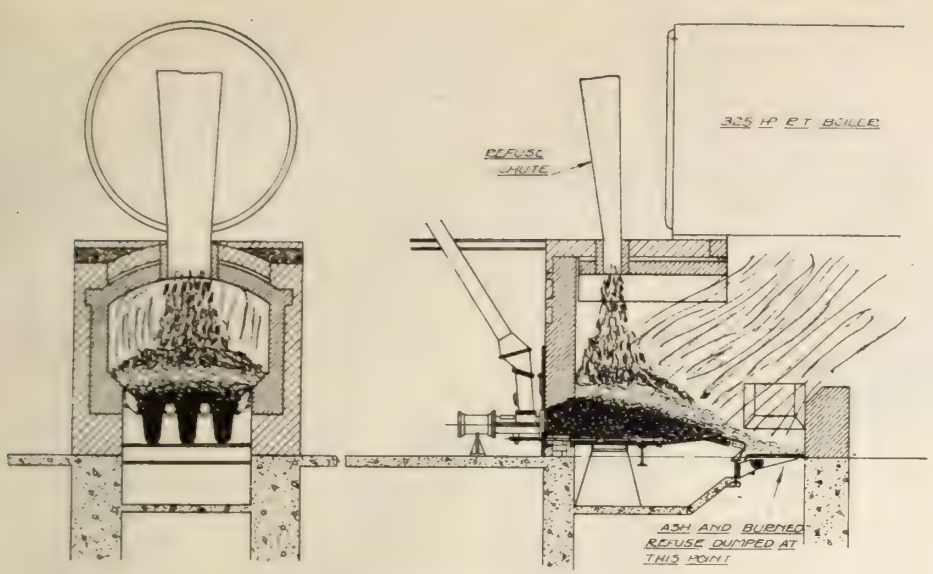

Fig. 3.—Stoker and furnace for H. R. T. boiler.

of the tapering holes over the dead plates. Thus the air must pass through the deep part of the fuel bed. With hand firing and forced draft usually the thin part of the pile is next to the wall and the air, naturally taking the path of least resistance, tends to blow holes through the thin part. With the stoker it is also possible to change quickly from hog feed and coal to straight coal in case there is a shortage of the refuse.

Burning Coal and "Hog Feed"

When burning coal and "Hog Feed" with moisture under 50 per cent. it is possible to obtain higher boiler ratings with the coal and refuse combined than when burning straight coal. At one plant, where the hand cleaning type of under-feed stoker was installed, to operate boilers with coal at 125 per cent. of rating the boilers have been operated up to 200 per cent. of rating continuously when burning coal and refuse. However, when burning straight coal, the boilers could be operated at only 150 per cent. of rating. In Fig. 1 is shown the hand cleaned type of under-feed stoker as applied to a horizontal return tubular boiler for burning "Hog-Feed."

In the majority of plants the bark from the barking machines is wasted and very often difficulty is experienced in disposing of it. In some localities laws have been passed to prevent dumping it into streams. It can be disposed of and a saving made by burning on stokers under boilers. It is being burned on the under-feed stoker with Dutch oven setting and return tubular boilers. At one plant the bark is carried out of the barking machines by a flowing stream of water from which it is finally separated and run through two sets of squeezers before being conveyed to the furnace. The bark is very wet, it being possible to squeeze water from it by hand. A sample taken showed 70 per cent. of moisture. It is of course, essential to burn a small amount of coal to get good results with this wet refuse. Fig. 2 shows the application of stoker to a vertical tubular boiler.

The standard hand cleaned type of stoker is particularly adaptable and has been extensively applied in burning refuse under the smaller size boilers of 100 to 300-h.p. However, for the larger size units, the automatic cleaning stoker is better adapted. It will not only burn large quantities of "Hog Feed" but it is possible to obtain high boiler ratings when burning straight coal.

Fig. 3 shows an installation of three long retort automatic-cleaning underfeed stokers, under 325-h.p. horizontal return tubular boilers. These furnaces have one feed hole for the refuse through the top of the extension furnace. Conveyors keep a continuous stream of refuse falling through this opening. At a test made at this installation the boilers were operated at 177 per cent of rating by burning 246-lb. of coal and 2550-lb. of "Hog Feed" per retort per hour. It would have been possible to have obtained even higher rating if there had been more stack draft. The refuse consisted of trimmings and edgings of spruce, tamarack and jack pine and sawdust.

Following are some of the results of a test on the above boilers when burning "Hog-Feed" and coal:

Boiler

Horizontal return tubular 90-in. dia.; 20-ft. long; rated at 325-hp.; 3413 sq. ft. heating surface.

Stokers—

Automatic cleaning, 3 long retorts.

Conditions

Steam pressure, lb. gauge	119.7
Temp. of feed water, deg. fahr.	229.0
Temp. of escaping gases, deg. fahr.	683.0
Pressure in air chamber, inches	1.6
Draft in furnace, inches	0.05
Draft between damper and boiler, in.	0.50
Carbon dioxide in flue gases, per cent.	14.8
Factor of Evaporation	1.002

Coal Analysis—

Fixed carbon, as fired, per cent.	48.96
Volatile matter, as fired, per cent	36.38
Ash, as fired, per cent.	10.65
Moisture, as fired, per cent.	4.01
Sulphur, as fired, per cent.	3.26
B. t. u., as fired, per cent.	12,362

"Hog Fuel" Refuse Analysis

Moisture, as fired, per cent.	41.65
Ash, as fired, per cent.	4.0
B. t. u. as fired, per cent.	4,220

Summary—

Coal burned per hour, lb.	245.5
Coal burned per hour, per retort, lb.	81.8
Refuse burned per hour, lb.	7,680
Refuse burned per hr., per retort, lb.	2,560
Water evaporated from and at 212 deg. per hour, lb.	19,914
Boiler hp. developed—average	577.2
Percent of rated capacity developed	177.6
Coal burned to develop one b. hp., lb.	0.43
Refuse burned to develop one b. hp., lb.	13.31
Pounds of refuse per cu. ft., lb.	16.67

Figs. 4 and 5 show stokers as applied to 500-h.p. water tube boilers.

Under the proper conditions when

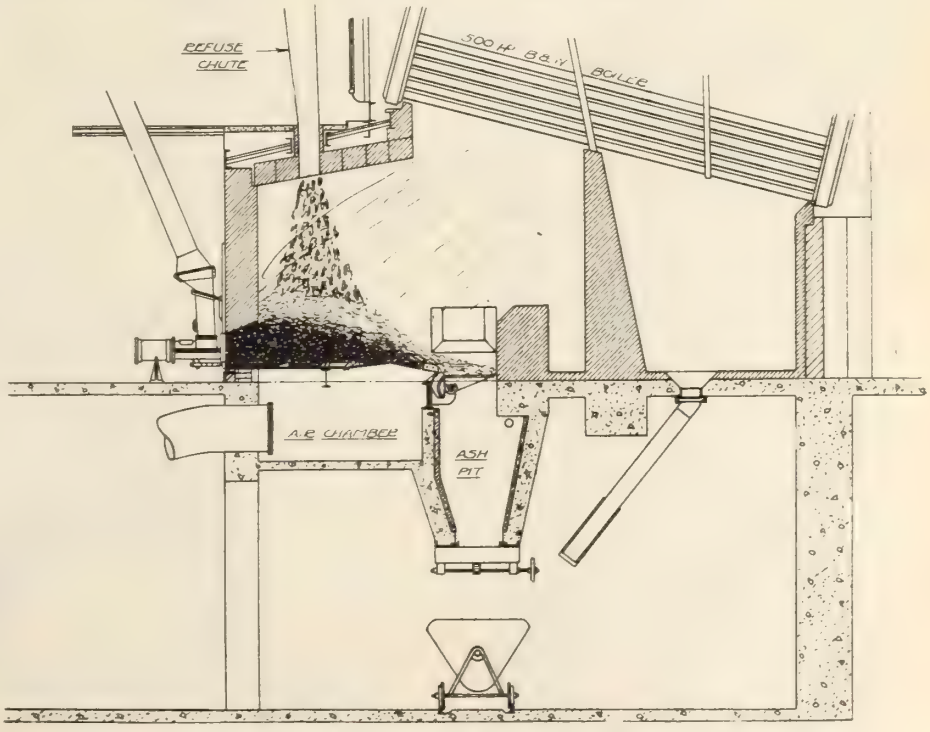

Fig. 4.—Horizontal water tube boiler equipped for hog fuel.

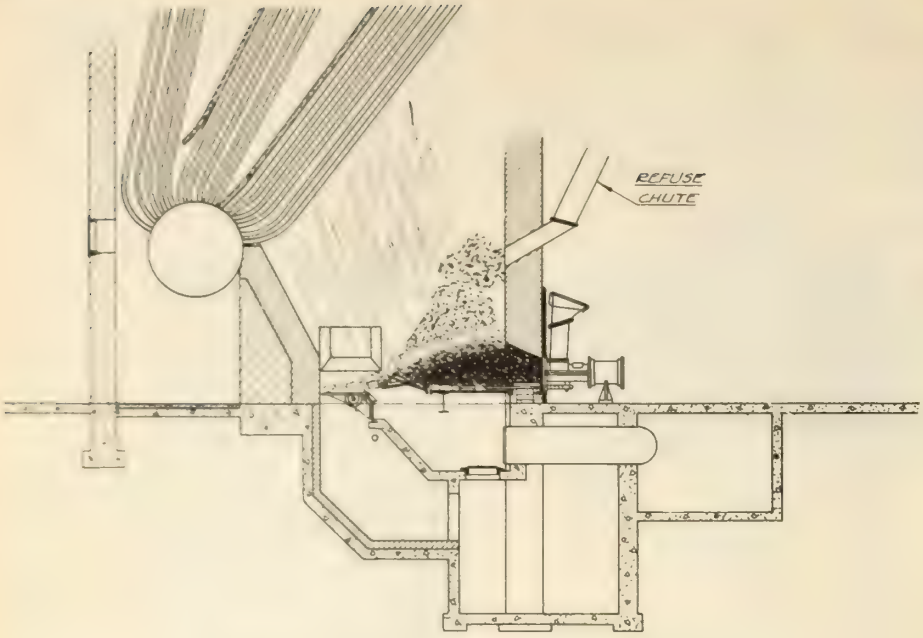

Fig. 5.—Vertical water tube boiler equipped for sawdust.

burning "Hog Feed" there is a very large volume of flame and the per cent. of CO^2 in gases is high. It is important that there be a large combustion space not only to obtain complete combustion but also to prevent unburned fuel being carried through the boiler.

Burning "Tan Bark"

Tan bark has been used for fuel on the standard type of under-feed stoker for several years. The spent tan consists of the fibre portion of bark which has been used in the processes of tanning. It ordinarily runs very high in moisture. The heat units per pound of spent tan usually average about 9,000 on a dry basis. With 65 per cent moisture, spent tan averages about 2,655 B. t.u.

The early practice in burning tan bark was to use a large Dutch oven furnace with ordinary grates. These furnaces usually had several holes in the top and the fuel was dropped through these holes on the grates. One particular type of furnace had a grate surface 24-ft. long by 6-ft. wide and the tan was fed through about five holes in the roof. Another type of furnace had a humpback grate. These grates were sloped to the sides of the furnace, with the high point at the center. This grate provided increased area, at the same time diminished the maximum thickness of the pile of fuel, (the feed holes being located over apex of grate) and thus insured a free air supply. A common trouble in these types of furnaces is the formation of air holes and the rapid burning away of the fuel next to the side walls which results in a large leakage of air from the ash pit.

For burning spent tan bark in large quantities with under-feed stokers it is necessary to have a Dutch oven with a comparatively low arch. The bark is fed onto the top of the oven usually by a conveyor, and dropped through feed holes either directly by conveyor or by hand on each side of the furnace. The bark piles up on the dead plates against the side walls leaving an open space over the stoker retort. A small quantity of coal is burned and the fire from it dries out and ignites the bark. The bark burns principally at the surface of the pile and over the stoker tuyeres. The bark is light when dried and will not stand a high air pressure. In this type of furnace it is possible to burn very large quantities of the bark and get good boiler ratings. Figs. 6 and 7 show the application of stokers to furnaces for burning tan bark.

At one plant it was possible to operate a 100 h.p. return tubular boiler at 188 per cent of rating. This required only 188-lb. of coal per hour and 2,400-lb. of tan bark per hour.

At another plant, where they do not have a very large quantity of bark, it is burned by feeding directly through the hopper, one shovelful of coal is fed in and then about seven shovelsful of tan bark. The stokers are set directly under the shell of the horizontal return tubular boiler and there is no arch. The stokers burn about 50 cu. ft. of bark per hour in this manner and consume the entire week's supply in about two days.

Burning "Sawdust"

Sawdust and shavings are available at most woodworking plants and have been common fuel supply for both

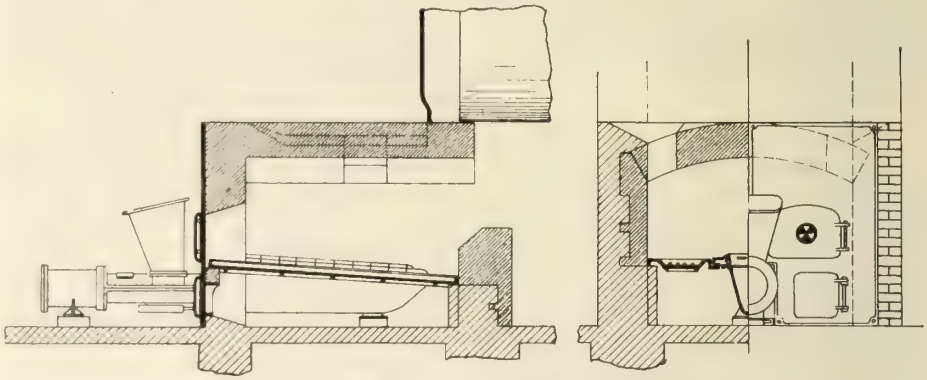

Fig. 6.—Return tubular boiler equipped for tan bark.

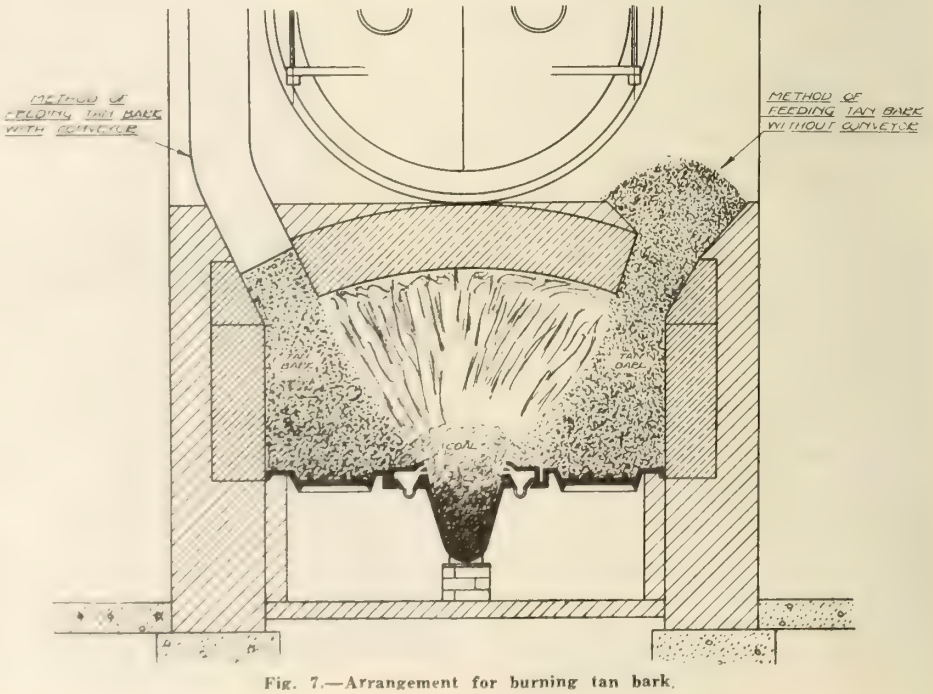

Fig. 7.—Arrangement for burning tan bark.

hand cleaned and automatic cleaning under-feed stokers. In burning this fuel no particular setting is required. The fuel can be burned in the ordinary coal burning setting, although best results are obtained when having a large combustion space. In the larger plants the sawdust, shavings and some of the hog-

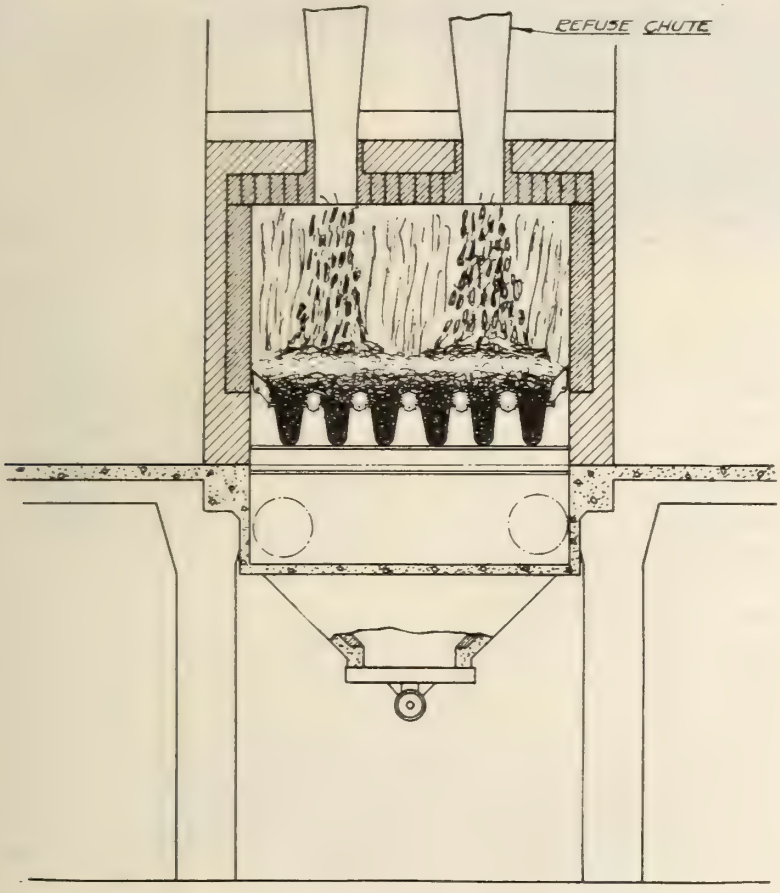

Fig. 8.—Equipment for burning hog fuel.

ged material is elevated to an over-feed receptacle by cyclone blowers and the fuel is then dropped by gravity through spouts which enter into the front of furnace.

At one plant where the automatic cleaning type of stokers are installed about 75 per cent of the refuse is burned in suspension, it being necessary, of course, to burn coal at the same time. At this plant the wood refuse supplies about one-half of the heat delivered to the boiler. Fig. 5 shows a water tube boiler equipped with stoker for burning sawdust and shavings.

At a few plants drug refuse is being burned. In one plant the stokers are set in a Dutch oven and the drug refuse is dropped in through holes at the side of furnace onto the dead plates. At other installations the refuse is fed through the door and piled on the dead plates.

Husks, hulls and chaff are available at food cereal plants and can be burned in a manner similar to sawdust. There is also considerable heat value in nut shells and this material can be readily burned. In fact furnaces can be designed to burn practically any kind of refuse that has heat in it. The under-feed stoker is especially adapted for burning refuse material due to the fact that a hot coal fire can always be carried under the material drying it out and igniting it. There is no tendency for the refuse material to smother the coal fire due to the under-feed method of feeding the coal. Under-feed stokers make the power plant operator more independent of the fuel supply, as it is possible to change quickly from burning refuse to straight coal.

DIESEL ENGINE USERS' ASSOCIATION

At the last meeting of the Diesel Engine Users' Association, held at the Institution of Electrical Engineers, Mr. Oswald Wans, A.M. Inst. C.E., M.I. Mech. E., read a paper on "Some Recent Developments in Mechanical Injection Oil Engines Using Heavy Oils." The author dealt with some of the outstanding developments of two and four-cycle mechanical injection engines which had been instrumental in rendering these prime movers efficient and reliable. In connection with two-cycle engines reference was made to the light-load running gear adopted by Vickers-Petters, Limited, by means of which a portion of the fuel is injected well in advance of the main charge, thus giving the pilot charge time to vaporise before the entry of the main charge. Fuel consumptions as low as about .55 lb. per brake horse-power hour—equivalent to a brake thermal efficiency of 25 per cent.—were mentioned as having been obtained with a fuel of about .9 specific gravity and 18,300 B.Th.U. per pound. Discussing four-cycle engines, the author referred to the advantages which had accrued from the adoption of increased compression pressures, and gave particulars of the performance of a Ruston and Hornsby engine with a compression of about 425 lb. per square inch.

The general progress made with solid injection engines during the past five years had been marked, and there was good reason to believe that the limitations of the high-compression mechanical injection oil engine had not been reached. Already engines were built developing a maximum power of 200 brake horse-power per cylinder, with a brake thermal efficiency of 35 per cent. at working load, and one might confidently expect to see in the near future multi-cylinder engines developing 800 to 1000 brake horse-power.

The further development of the oil engine, whether of the mechanical or air injection type, was largely dependent upon the materials at the disposal of the designer, and the production of metals having greater heat-resisting properties demanded the close and continued co-operation of the engineer and the metallurgist.

The Engineering Experiment Station of the University of Illinois, has issued a bulletin, No. 124, entitled "An Investigation of the Fatigue of Metals." This is a progress report of the first part of the investigation, having for its object the determination whether or not there exists any clearly defined relation between static properties and ability to resist repeated stresses. It having been decided not to enter the field of non-ferrous metals at this time, a series of tests of materials well scattered over the field of ferrous metals was made, and in most cases two or more distinct heat treatments for each metal were studied. The results of the tests, and the conclusions to be drawn therefrom are given in the above mentioned bulletin, copies of which may be had without charge by addressing the Engineering Experimental Station, Urbana, Illinois.

Hoping to find oil for several years past the Commonwealth Government of Australia has offered a reward of £50,000 to the discoverer of a payable oilfield in Australia. In addition the New South Wales Government offers a reward of £10,000 for the production of the first 10,000 gallons of natural mineral oil within the state. The oil position at present is that scouts are out in almost the whole of the four quarters of Australia hunting for the faintest indications of its presence, and bores have been put down in places where favorable features have been located.

Our Plans For 1922

"POWER HOUSE" wishes its readers a "Happy New Year," and takes this opportunity to lay before them some of its program for the year 1922. The readers of a paper such as this have many diversified wants, but all tending in the same general direction, and in order to cover as many of the leading subjects as possible, we are introducing a series of special articles which will appear in each issue throughout the twelve months.

These articles are divided between four subjects, which will have six articles each. They are as follows: Six articles dealing with the internal combustion engine, six articles on refrigeration, six articles on combustion and recording instruments, and six articles on heating and heating apparatus.

In addition to these articles, a series of articles by Robert June dealing with the absorbing question of power plant costs will be run and should prove of great interest to all engineers who are in executive positions or aspire to same.

We hope that the "Question Box," which has proved such a popular department in the past, will continue to be of service to the readers of "Power House." As a matter of fact, it depends entirely on readers themselves as to whether this department is helpful or otherwise. All the queries that are answered in this section of the paper are actually sent in by readers, and if these queries do not come in, the section is omitted. We know that in some journals if the questions do not come in from the readers that the staff propound questions and answer them in order to fill up the space. We feel that no useful purpose can be served by such practice, and indeed have so far had no occasion to resort to it. At the same time we feel that for readers in general, as well as those who send in the queries, this department is one of the most useful in the magazine.

Another department which is devoted to the personal use of the readers is the "Operator's Point of View," which is open to any reader who has an idea to share, or a question to bring up which is of interest to the engineering world. There is at present a discussion going on which seems to have evoked considerable interest, on the question of the adoption of a "Dominion" certificate.

We started this discussion because it has always been our opinion that the system of local certificates was a burdensome one, and a Federal certificate would be better all round. The character of the letters coming in, a number of which appear in this issue, show that there are others who share this opinion, while of course the other side has been heard from. The general developments in the engineering world as disclosed in the discussion of the technical societies, and available in the form of papers read, will be published from time to time, when the discussion is of interest to power plant men. These papers are usually prepared by gentlemen of very high standing in the engineering world, and therefore are well worthy of study by those interested in the subjects treated.

With the foregoing we hope we have outlined a program that will interest our present readers and bring many new ones into the circle. We will be in the future, as in the past, always open for suggestions or criticism from our readers, which will receive our earnest attention. The success of a magazine depends as much on its readers as on its publishers. Each must do their part. Gentlemen, let us go forward together, improving our standards as we go, so that at the beginning of 1923 we can look back on a year of good work, and forward to a year of better.

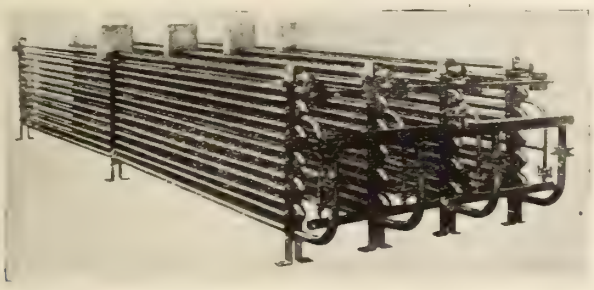
Progress in New Equipment

PREVENTING AMMONIA LEAKAGE

Ammonia leakage, if for no other reason than the loss it represents in dollars and cents, is serious enough to demand attention, but because such leakage involves danger to human life, it is of utmost importance that every precaution be taken to avoid the possibility of trouble.

Most engineers are familar with the usual construction of joints in ammonia lines, and in the return bends of condensers. Joints at many points in the ammonia system can be eliminated. There are points, however, in present construction which can probably be improved. For example, where welding can be used, it is advantageous to do so, because it overcomes the necessity of a joint and eliminates the chances of leakage at that point.



A Stand of condenser coils.

A still greater insurance against ammonia leaks is claimed in the condenser coils manufactured by the Superheater Company, Limited. The feature in these coils is the return bend. In this bend no threaded, electrically or acetylene welded joints are used, and still the return bends are actually stronger than the body of the pipe of which the condenser coil is made.

This return bend is a forging formed in a special forging process out of the metal of the pipes themselves, by means of a special forging machine. By means of this construction, a continuous pipe from inlet to outlet is possible and at the same time, the shortest possible return bend is effected without excessive pipe friction. Cross sections taken through the return bend discloses that there is no reduction in cross section area of the bend.

It will be readily appreciated that a greater cooling area is possible within a given space than is found in any other type of condenser coil.

Another advantage of this construction, is, as will be noted from the illustration, that only one valve is necessary on each header to control a unit of four stands, instead of three valves on each stand, which are necessary with built up coils. The elimination of valves means the elimination of other points where leakage might occur, and the leakproof feature of these coils eliminates the necessity of shutting off a coil for repairs.

Another advantage of this construction is the fact that because of the close spacing of the pipes, the drip strips ordinarily used to facilitate even water distribution are found to be necessary only between the water trough and the top pipe.

These coils can be made to practically any specification and are tested to not less than 800 lbs. hydrostatic pressure before shipment.

Showing Return Bends

NEW FLUE GAS FILTERING SYSTEM

Every boiler operator familiar with CO_2 equipment knows that the first requisite for successful operation is cleanliness and complaint is sometimes heard of the time required for blowing out the gas sampling lines and keeping the mechanism in clean condition. Realizing this situation the Uehling Instrument Company, 71 Broadway, New York City, have been experimenting with many substances to perfect means for completely excluding soot and dirt from the gas sampling line.

Finally a material combining the necessary porosity and refractory qualities was found and this is now embodied in the new Uehling "Pyroporus" filter "A" which is placed on the inlet end of the gas sampling line inserted in the flue or last pass of the boiler furnace. This filter consists of a heavy but highly porous disc held in a cup-shaped casting by means of a bolt. It is not injured by very high temperatures.

Formerly the gas was withdrawn through an open-ended pipe and the filtering was accomplished with cotton waste; this necessitated more or less blowing out of the gas line and required frequent renewal of the filtering material. With the new arrangement, the soot builds up on the "Pyropous" filter and does not appear to enter the pores to any extent, in fact many of these filters have been in service for months without ever having been blown out or replaced and without apparently offering appreciable increased resistance to the gas flow.

It is not yet known what life may be expected of these filters but present indications are that they will last for several years without any attention whatsoever. They are, however, inexpensive and are easily replaced. To facilitate inspection and replacement the manufacturer has also developed a frame to be inserted in the brickwork and a holder for the sampling pipe. It is quickly fastened in place by two bolts. By loosening the nuts on these two bolts and by unscrewing the union at the bottom of the section of sampling line, it requires but a moment to withdraw the filter through the frame. The frame is the width of two bricks hence it is a simple matter to insert it in the setting without cutting a large hole in the brickwork. When the sampling line is to be inserted through a metal casing,

The Operators' Point of View

INDICATOR DIAGRAMS

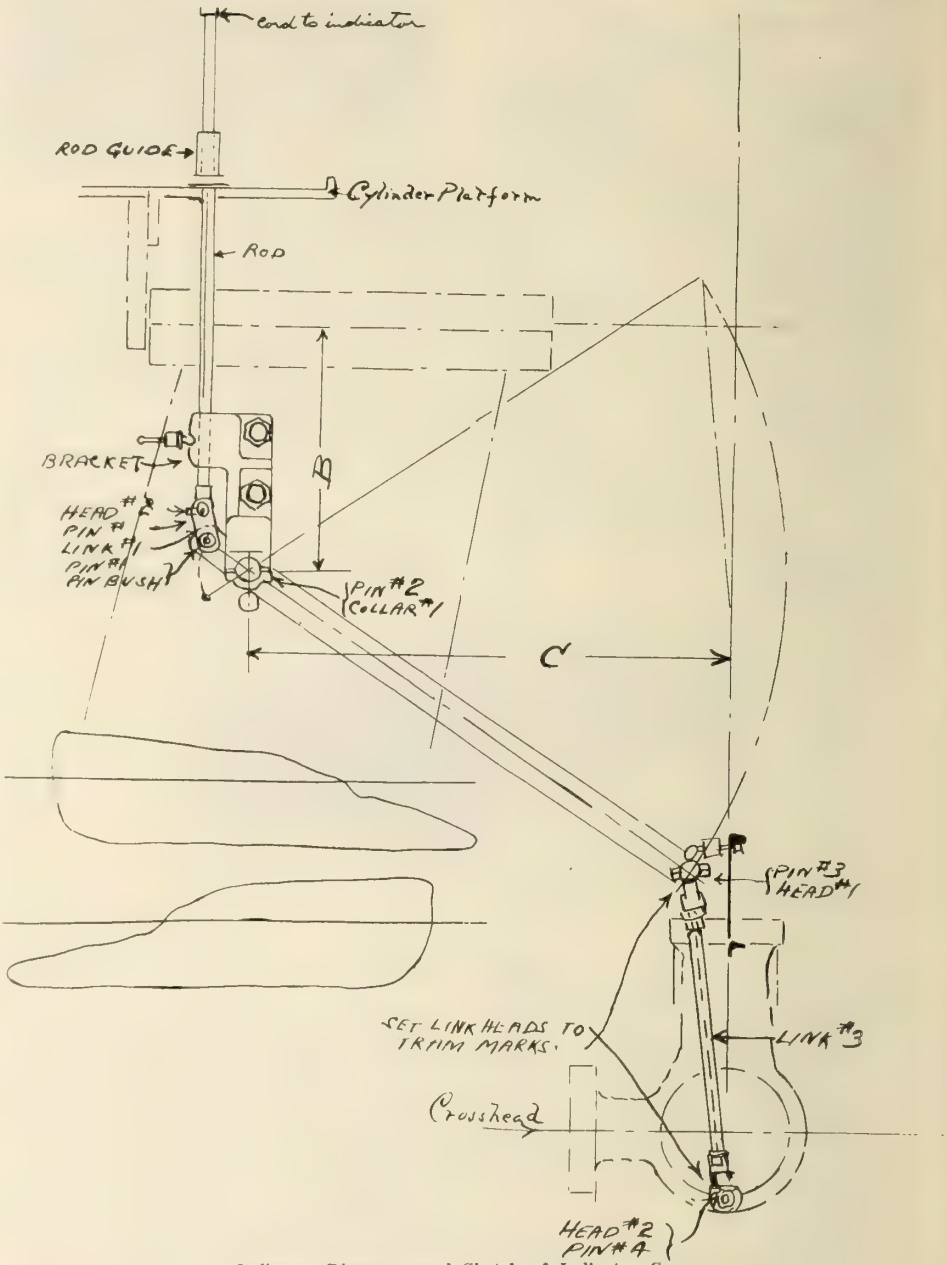
The Editor,
"Power House:"

In your issue of Nov. 21st, I took notice of a pair of indicator cards which had been drawn without lifting the pen. This may have been done using a carbon copy between the original and the copy, but what struck me more forcibly than anything, was the rise in the expansion line. Our Editor places the fault on the indicator, probably this may be right, but there is another answer to that as well. A very uneven and fluctuating load will sometimes cause that to appear on a card, when a short circuit, or "flash over" has occurred on the generator, during the time the card was being taken. This is an opportunity for the opening up of some very useful discussions, and I am contributing two more cards with the expansion lines forming indentations. Some probably would put it down to indicator fault, I did so myself at first, and changed the indicators. I was setting valves on the different engines, after repair to links, etc., and had four indicators in use, on both the engines, low pressure cylinders, I got the same result. After a careful search, I found the indicating gear attached to the engine was the cause. Our Editor has had considerable experience with the same class of engine, probably he can give us a few points on the subject. I enclose sketch of indicating gear and point out the fault in same which in my opinion might be altered to a more positive motion. I think if the long rod was carried to the full extent on the crosshead side, instead of having the small rod between, and have the long bar slotted to take up the tangential curve, the same could be done on the other end of the rod instead of links, we should have a more positive transmission of forces, I think you will agree that any slight play in the pin on links will show itself, when in its two extreme positions. I am not trying to explain the action from a dynamic point of view, but from a plain, practical engineering standpoint.

Yours truly,
Henry Wright.

Editor's Note

In the case of a sudden rise or drop in the expansion line of an indicator card I am convinced that any lost motion in the gear can cause it. The tendency for any distortion of a card through lost motion in the indicator gear is to distort the card at either end.



Indicator Diagrams and Sketch of Indicator Gear.

As the gear moves in one direction throughout the stroke, any lost motion will naturally be taken up at the beginning of the stroke in each direction.

A sudden load coming on the engine during the expansion stroke such as Mr. Wright mentions would tend to a momentary rise in pressure causing a hump in the expansion line. through holding the piston back during a small instant of time before the momentum of the flywheel came to the rescue.

Suppose the drum of the indicator did not revolve at all during the expansion stroke, the line traced would be a vertical one, from the initial pressure height to the final pressure height. Any momentary stoppage of the drum through lost motion in the gear during the expansion stroke would show a straight drop from the expansion line curve, the curve resuming at the lower level but in its natural direction. When on the other hand the expansion curve stays

at the same level for a definite space of time, making a line which is horizontal, or if the curve raises above its level, it seems to me to indicate definitely either a holding up of the piston through some mechanical cause, or through a sudden increase of pressure due to a momentary increase in the load on the piston.

In indicating engines with the gear here illustrated by Mr. Wright I have never had any experience of a hump such as shown on the cards in the illustration.

Re Mr. Wright's suggestion as to the slotting of the link to avoid the complication of swinging links, I think this might be done, but think that in this particular gear the wear on the pin and slot would be greater than in the arrangement shown. Mr. Wright doubtless remembers the indicator gear on marine engines, where the only support was a pin on the back column, the indicator bar being slotted where it went on the crosshead, or else two bars are used, with a telescope arrangement to take up the movement caused by the radius of the indicator rod. In the case of the low pressure cylinder, the air pump levers furnished a convenient means of reducing the crosshead motion, without any other reducing gear.

Have any of our other readers some experience along these lines to help the discussion?

DOMINION WIDE CERTIFICATE

The Editor, Power House.

I thank you for your small editorial note on page 38 of last issue of Power House, and will try and refrain from any future personalities. I do not think in my letter of this issue that any fault can be found with the tone, and I will promise to refrain from such bad habits in the future. I thank Mr. Noble most sincerely for his kind remarks on my behalf, he like myself, has seen the futility of indulging in personal and childish criticism, for it not only is the cause of young engineers being afraid to air their experiences in public, but leaves a bad taint in the public mouth, with regard to engineers in general.

I am following with interest the discussion which is appearing in Power House under the title of "Dominion wide Certificates," and think if this could be adopted would be a boon to engineers of Canada, but until you can destroy the petty jealousy of the younger grade of engineers, it will never mature. I don't wish to appear pessimistic in the assertion but, I make the statement boldly, knowing full well that I shall bring an avalanche of protests and abuse on my poor head by so doing. The reason our stationary engineers are in the position which they today hold is through lack of education. This causes ignorance, and through ignorance comes petty frivolities in our bearing to each other. Do away with these and you will form more of a spirit of "Camarade" between the different provinces. This may be brought more forcibly to our minds by the few words spoken of in Mr. Moore's letter of Sarnia: "The engineer who is well up in the standard of perfection has a certain amount of pity and in some exceptional cases, contempt for his brother engineer who is not so fortunate, also the engineer who passes a more strict examination in Ontario, holds the engineer of Quebec in the light of pitying patronage," and so on. Now, take the higher grade of engineers. Do they piffle with one another over trifles? Decidedly not. They cover up one another's faults like doctors, etc., do. This should be the stationary engineer's standard also. I am merely writing this article to set up a good controversy, and I hope the aftermath of these discussions will cause the powers that be to sit up and take action.

I would like to make a suggestion in regard to Mr. Goepel's letter. A man leaving and going to another province could always have a copy of his examination papers forwarded by the inspector of the province he has just left, to the one he is going to, and this set of papers could be passed from province to province as the engineer in question moved about, the original papers to be kept in the office of the province in which he first passed. This would mean a little extra work for our provincial examiners, but in the interest of the engineering community I think they would not mind, especially if a little extra remuneration was added, and the provincial government could well afford that, from the amount of money they gather each year from the various license holders.

There is at present a scheme on foot for an inter-provincial set of regulations as regards boiler construction. This was printed in 1920, and I have a copy before me with the names of the different delegates at the conference. This set of regulations in general is combed from Lloyds' rules and regulations, and if this can be carried through why not the nation-wide certificate? I shall await with interest any further discussion on the matter.

Henry Wright, A.M.E.I.C.,
Montreal Tramways Co.

The Editor, Power House:

In your issue of November 21 I read a letter under the heading of "A Challenge Accepted." Now I think the reason a great many of us do not attempt to answer such queries is that we do not feel ourselves competent to give a thoroughly correct answer, and such being the case, we would much rather not write at all. By being mum on the subject we are much better listeners to the sayings of wiser men than ourselves and we gain knowledge thereby. As regards the argument re a "Dominion-wide Certificate" I do not think our Editor wished to convey the impression that any of our examiners were dishonest, only that such might be the case. Last winter I was in charge of one shift in a factory power plant, there being two other eight hour shifts under a separate engineer. Now one of these men held a licence, the other did not. One day we were visited by an inspector on my shift. The manager accompanied him, and I heard the manager tell the inspector that a certified man was in charge of each shift. Now that inspector is an honest man but he was misled as many others are.

I also read on page 38, Dec. 5th. issue, the Editor's note. He is right, gentlemen, as to that other correspondence. One letter was mine and I have been ashamed of it ever since and hereby apologize to those to whom an apology is due. Let us all be friendly and thereby help our paper.

W. H. Long.

The Editor, Power House:

We have read many comments upon the Ontario Certificate. Now comes forward the idea (which is a good one if carried out strictly) of the Dominion Wide Certificate. I am expecting to see many letters expressing the pros and cons of this idea in future issues of Power House.

May I express my view? To me, the engineering profession in Ontario is not looked upon as it ought to be, the Engineer is not given the credit he should be, that is to say, that our employers, in the majority of cases look upon us as shovelers of coal, belonging to an uneducated class with a "strong back and weak mind" and offer us pay in accordance with their views, for, what is the average pay of a 2nd class Engineer? Take this case that I know of. The Engineer works 10½ hours per day. He does his repairs outside of this time for which we will make an allowance of 1 hour a total of 11½ hours daily for which he receives $5.00—a magnificent sum of 43.48c per hour.

Another position I applied for myself. The manager offered me $30.00 per week. I had to do my own firing, with shavings, to have steam up ready to start the engine at 7.30 a.m., shut down at 5 p.m., I would then have to do what cleaning was necessary. Work until 1 p.m. Saturdays and wash a boiler every Sunday, repairs to be done outside of this regular time without pay—probably in all about 75 hours per week or 40c per hour.

Since then I understand the pay has been reduced to $27.50.

Is this a position for a 2nd class Engineer? Is this 2nd class Engineers' pay? We buy books of a technical nature, (when we can afford it) we subscribe for technical publications and perhaps we attend technical school. While at work we use the knowledge thus gained to try and save our employer dollars and cents. Why? So that he may pay us the princely sum of 43.48c per hour.

Just today I was studying an article in Power House, "How to make use of Logs," and paused long enough to ask myself the question, Is it worth while? When one knows that the men who empty the garbage for the city get 60c per

hour, carpenters and bricklayers over 75c, have we not the right to pause and ask, "Is all this study worth while?" Under the existing conditions I would say, "No."

We must have 10 years' practical experience before we may have the privilege of writing for a 1st class Certificate, then we must pay $10.00 for that privilege and $2.00 per year for renewal.

What is the cause of our position?

1. Too many Certificates issued (without examination) when the graded law became effective, resulting in a large number of men holding certificates who, if now asked to pass the required examination, would utterly fail.

2. A large number of Engineers are holding positions which call for a Certificate one grade higher than that which the Engineer possesses simply because they happened to be in that plant previous to the new law becoming effective.

The majority of them will hold their job "until the boiler busts," they are a hindrance to the man who is anxious to get ahead, because (a) they draw pay for the Certificate they hold, which is a grade lower than the job calls for. This satisfies the average employer and tends to keep the wages down elsewhere because (b) an Engineer with the necessary Certificate cannot get a position that his Certificate entitles him to because the fellow with the lower grade has it.

3. Lack of strict enforcement of the Law.

Regarding No. 1, I claim that every one should have been required to pass their examinations for the Certificate they were granted within a year or at most two years after the coming into effect of the Act thereby giving everyone a fair chance and no one getting favored accidentally or otherwise.

Regarding No. 2, each Engineer who is thus situated ought to be compelled to qualify for the grade of Certificate his position calls for or relinquish said position in favor of the man who holds the required certificate. A certain firm in this city has a power plant of approximately 800 B.H.P. A Chief Enginner in charge with four assistants on 8-hour shifts, three of these assistants carry 3rd class certificates because they were there when the Act came into force, the fourth has 2nd class papers, he was hired after the Act was passed and was therefore required by law to have a 2nd class, yet he had to work at the same rate of pay as the man with 3rd class.

Is this right? I do not wish to insinuate that a man holding 3rd class knows less than one holding 2nd class for sometimes the case is reversed, then in that case why doesn't he "scrap" his 3rd for a second?

Regarding No. 3, there have been some new laws passed governing Engineers which are a little stricter. A rigid enforcement of these laws would be one of the greatest boons to the engineering profession, (I use the word Profession because that is what the "trade" ought to be called) that can ever come about. In conclusion, I say, let us have a Dominion wide certificate. Let us have a Dominion Wide certificate. Let than than the late election. Let us have a still stricter law, a stricter examination and a more rigid enforcement, all these can be incorporated under "A Dominion Wide Certificate." If we get these then we may know that although we get only 43.48c per hour now, in the future we shall be rewarded.

Ten years is too long to wait for a 1st certificate. Ten dollars is too much to pay at the present rate of pay and the standard of the certificate is too low.

The Dominion Wide idea should appeal to all. Minor differences that might exist between provinces could easily be adjusted to suit all.

There are a good many engineers that when the 2nd or 1st certificate has been gained they would have something worth while.

Reading in Power House a report of an address given by Mr. Brown, Chairman of the Board of Engineers, at a banquet given by the C.A.S.E. he remarked that he hoped to make the Ontario certificate second to none. We can achieve this by the Dominion Wide Certificate.

"Hygrade"

The Editor, "Power House":

I have read with interest your editorial in reference to this matter, also letters replying to same by Mr. P. Goepel and Mr. F. Moore.

Mr Goepel writes that "permits or temporary certificates are very seldom granted." Ten years ago or even less, I could have agreed with this statement, but not at the present time.

Less than two years ago I was engaged as a shift engineer in a plant in B. C., having a boiler H. P of about 300 and equipped with steam-electric and Ice-making machinery, deep-well pumps, etc.

At this time there were many qualified engineers holding certificates available as times were dull. Notwithstanding this fact, a man with a temporary certificate good for six months was engaged at a salary considerably higher than the average paid in the province at that time.

He admitted to me, amongst other things, that he had never filled a sight feed lubricator, and did not know how to do it. Still he made it stick for the six months—the chief being about on a par with him thought he was O. K.—after which time he quit rather than try the examination which would be required of him if he was to be allowed to continue. A flunkey around the institution then obtained a temporary certificate good for twelve (12) months. He also pulled out in time to escape the examination.

Neither of these men were engineers, nor was the man in charge of the plant who is the holder of a third class certificate, and who pulls off such stunts as sending a motor away for repairs without knowing what was the trouble, when all that was wrong, was, that he had allowed one of the bearings to go dry on his own shift, causing it to seize the shaft stopping the motor. When asked by the electrician what was the matter with the motor, he replied, "that is what I sent it to you to find out."

Now the point is this. None of these men were entitled to have permission to operate power plants. Why they had such permission is beyond me. All three are returned soldiers, and obtained their certificates since they were discharged from the army.

What I consider as one of the faults with regard to the issuing of certificates to engineers in B. C., is, that a part of the examination is verbal, there not being sufficient written record of the candidate's qualifications kept to prove that a certificate ought to be granted to him, with the above mentioned result.

In Saskatchewan the whole of the examination is a written one. Not necessarily in the presence of an inspector of steam boilers, I wrote mine in the office of the Deputy Minister of Public Works. The work was then sent to the chief inspector of steam boilers and machinery and kept as a permanent record. This, I consider a far fairer and more thorough method as regards a Dominion Wide certificate no greater expense than that envolved at present is necessary, as the candidate could write his examination in the presence of any responsible government official and the work forwarded to a qualified examiner to be examined and passed upon.

I believe also that 3rd and 4th class certificates could well be dispensed with, shift engineers being allowed to operate under a holder of a 1st or 2nd class certificate, the examination for such certificate being of such a standard as would assure the holder's ability to judge as to whether a man can make good as a shift engineer or not.

J. G. Livingston,
Kamloops,
B. C.

The Editor, "Power House":

Permit me to express my opinion on this very interesting discussion. It is interesting to me for this reason that I do not possess any Canadian certificate, although, (pardon my egotism) I might have half a dozen of them if I cared to. Personally I do not think that Stationary Engineers' Certificates, as I know them, are worth the paper they are printed on. I have assisted, and coached more than a dozen young men to procure them and am doing so at the present time, but, after all, and plus a certificate, this will not make them engineers.

I remember some years ago, when I was at sea, a young man with his chief's ticket, (I was on watch with him as

junior) putting a hose on to a hot eccentric strap to cool it, with the result that the eccentric connecting rod 5in. in diameter broke 12in. above the strap causing considerable excitement and, incidentally, damage in the engine room. At the enquiry which was held after we got to port (I was one of the principal witnesses) I was asked by the Superintendent, "If I did not know anything that was better than a hose for a hot strap, and what I should have done under the circumstances?" I told him what I thought should have been done. He (the super.) then gave the chief a lecture, which I have never forgotten and told him always to remember, that although he was chief, that there were probably better engineers round about the engine room than he was. Needless to say that chief did not sail with us next trip. I have mentioned this to show that a certificate is not much good unless you have considerable experience to back it up.

I am of the opinion that a Dominion Wide Certificate would be the best, for at least one reason. Supposing, as was the writer's experience, that a position is open, say out somewhere in Western Canada and an engineer, say in Nova Scotia applies for it. This engineer has been in Nova Scotia all his life and possesses 1st class N. S. papers. How is the engineer to know if his N. S. papers are the equivalent of the papers out there in Western Canada? I have heard it said that N. S. papers might land a good fireman's job up in Ontario, I took this with a litle salt, of course. I am personally acquainted with several good N. S. engineers up there. Would not a system like the British Board of Trade be better, where every ticket has the same value all over the world? The question of identifying the holder of a B. O. T. certificate is easy. Any engineer knows that there is marked on his Discharge Certificate, his name, where born, height, complexion, peculiarities, tattoo marks if any, color of eyes, hair, etc. So that any one trying to get by on a certificate not his own, has a job to do it. If a certificate is lost, and is found by anyone, he is instructed (on the ticket itself) to return it to a certain address, or to the nearest Board of Trade Office where a substantial reward is paid to him for its return. I have myself, lost my own, on two occasions in one of the largest shipping ports in Britain and have had it returned to me by the B. O. T. officer when "signing on" for our next voyage. Something then along these lines would be a help towards a better system of dealing with "unknown quantities." I remember shortly after I came to Canada and even although I had a certificate from the British Board of Trade to show my "bona fides" as an engineer I wished to get Canadian Papers. I was informed that I must first get a third class ticket, wait for a year, get a second class ticket, then wait for another year before I could take 1st class papers. I got into communication with the Chairman of the Examination Board and enqiured if it were not possible for me to take a 1st class examination at once. He informed me that I could not, and that the above regime was in force. Formerly, he said, it could be done, but not now, I would probably have to get permission from Ottawa for this and would have to pay all the expenses of a special examination. This I took to be rather hard lines, and have not bothered with it since. A system should be recommended so that anyone could take an examination for 1st class papers at any time, and anywhere, provided he can show the Government Examiner verbally that he is fit to do so.

Mr. Goepel, in the last paragraph of his letter says, "The local conditions peculiar to themselves is one factor which would be difficult to overcome with an All Canadian Certificate." This is probably correct, then why not an examination extensive enough to cover all kinds of plants? That is, at least for 1st class papers. There is a great difference between logging camps and municipal lighting, coal mines and shipping and so on, but all generate steam in a boiler. Hence the usual boiler questions would remain. The modern tendency now is the Turbo Generating Plants and Electrical equipment. I do not recollect having seen any questions along these lines, at least not in this province, for the past eight years. In the "Old Country" things are done differently. Before anyone can go after a certificate he must first have served his apprenticeship of 5 years as a "fitter" (called "machinist" in Canada) before he can even get a job in an engine room. Here in Canada anybody can go and sit for papers and get away with it, and the result is mediocrity. I am speaking from personal experience with this class. A young man in this district ran away from home here and went to London where he got a job on a ship as a greaser (oiler). After making a trip or two, when he found that he could not "rise to be an engineer" he gave it up and came back home again. He found out that engineers were not made that way, at least, not in the Old Country.

If anyone will look through any British Technical journal and see there an advertisement for an engineer, he will invariably find added to it: "Marine Engineer preferred." Why is this? The advertiser knows that a marine engineer has been properly trained and examined and that there is no doubt about his certificate as stated above.

I do not wish to be misunderstood. I am not trying to compare the British Board of Trade certificate with the Canadian certificate and, I think, anyone who has had experience with both, will understand why. I only wish to point out that a Dominion Wide certificate in the lines of a British Board of Trade certificate would be a far better arrangement than the present system.

J. W. C.

A CHALLENGE ACCEPTED

The Editor, "Power House":

Under the heading, "A Challenge Accepted," Mr. Wright replies to a former lettter of mine which was printed under the heading "A Challenge," which was not written with that idea in view but for an entirely different purpose. However, the purpose has been accomplished.

Mr. Wright's letter deserves an answer.

In the first place, I was not complaining of lack of courtesy by Mr. Wright in not replying to my letter in answer to his question regarding the tube failure, at least not in the sense that I wanted or expected thanks. There is another reason possible and it is the correct one.

In a letter I received a few years ago from the late Oroses C. Woolson, a New York engineer, Mr. Woolson complained of the invariable neglect of engineers when asking for help through engineering magazines to acknowledge any help given. Not that he wanted thanks for the help, but he did want to know if the help offered was of value in the case, that is, if the solution offered was correct. The pages of an engineering magazine may be used by engineers for their mutual benefit, but this benefit can be enjoyed most if those asking for help will say which solution was the correct one instead of, as Mr. Woolson stated, "closing up like a clam." It is just possible that "closing up like a clam" is what discourages engineers from offering help.

I remember Mr. Wright's question about the Rado-jet and did not answer it because I had no "guess." If Mr. Wright will be good enough to send me a copy of the reports on the tube failure I would appreciate it very much, not altogether because I want to know the right answer, but because I would like to know the process of reasoning by which they arrive at their conclusions.

In regard to my questioning such an authority as Mr. Pratt, Mr. Wright does not appear to be quite clear. It is only his common explanation that I do not agree with. Another common explanation that I do not agree with is that of the cause of smoke, viz.: that it is caused by the hot gases striking the cooler boiler surfaces, before combination is completed becoming cooled, and depositing the soot.

The true explanation as found by the U. S. Bureau of Mines, is that smoke is formed at or near the surface of the fire, and remains smoke until it either finds sufficient oxygen to make CO or CO_2, or is deposited on some part of the boiler, or passes out the chimney. There are some common explanations that ought to be in the discard.

Anyway, why should not I question Mr. Pratt's theory in so far as his "common explanation" goes and on which he does not appear to be very much struck himself, when other authorities go so

far as to say that excess air lowers the exit gas temperature, which is directly contrary to Mr. Pratt's claim?

If my action constitutes bravery what would Mr. Wright say about the latter?

Now Mr. Editor I don't think I have said anything to hurt Mr. Wright's feelings. And even if I have I know he will not call me names.

The fact that he was disheartened and even disgusted indicates that there is something wrong about the way that engineers play the game.

One thing I want Mr. Wright to understand clearly and that is that I don't subscribe to the creed "what we have we hold" and I don't think he does.

R. McLaren,
160 Dovercourt Road,
Toronto.

BOILER HORSE POWER

The Editor,
The Power House.

Dear Sir:—

The writer feels that Mr. McLaren's letter in your issue of December 5th on Horse Power and Boiler Rating was timely and of interest to engineers in general, because there are still some engineers who cannot understand the fact that a boiler of definite Horse Power will not always supply sufficient steam to an engine of equal horse power rating, or on the other hand may be made to deliver a far greater horse power at the engine shaft than the rating of the boiler.

Mr. McLaren deplores the fact that Steam Plants are rated in the way they are for the purposes of Engineers' Certificates in Ontario. Mr. McLaren apparently forgets that the term Boiler Horse Power is in any case a purely arbitrary unit of measurement, which has not been standardized by Act of Parliament or International Agreement as have the Centimetre, the Pound, the Gallon, etc. Therefore any one is at liberty to define this unit in any way he feels fit for any particular purpose, but in order that another person may know just what he means by this unit he must give his definition of the unit. This has been done in the case of the "Regulation Relating to the Examination of Engineers;" also, the B. H. P. has been defined in another way in the "Regulations for the Construction and Inspection of Boilers;" although both these publications are issued by the Department of Labor of the Ontario Government. Other provinces such as Alberta and British Columbia define Boiler Horse Power in still other ways, each for its own purposes.

Mr. McLaren seems to feel that the Boiler Horse Power unit for the rating of steam plants in Ontario should be more nearly equal to the usual builders rating, viz. 10 square feet Heating Surface per Horse Power. The writer feels that the reason for the low rating of this unit by the Board of Examiners is to make things as easy as possible for Engineers, also to prevent engineers complaining that their plant is too highly rated and that they should not be required to hold such a high grade of certificate.

In illustration of the above, consider a boiler plant with Return tubular boilers having a total of 2985 sq. ft. Heating Surface. Under the above mentioned regulations this would be rated as a 199 Horse power plant, and would require therefore only a 3rd Class Engineer in charge. However, with good firing and draft, these boilers would no doubt develop about 350 Horse Power (measured by evaporation), which with modern high efficiency engines would develop well on to 500 Brake Horse Power. All on a 3rd Class Certificate. This gives the engineer in charge no chance to complain, and gives good openings to the lower grades of engineers. Thus the requirements are not really nearly as high as they seem on the surface.

If the above plant had been rated at 14, or less, sq. ft. Heating Surface per Horse Power, it would have required a 2nd Class Engineer to take charge, because it would have worked out at over 200 H. P.

I might mention here that the American Society of Mechanical Engineers have for some years past discontinued that use of the Boiler Horse Power as a unit of capacity in favor of a standard unit of one pound of water evaporated into dry steam from and at 212 degrees Fahrenheit.

M. B. Watson.
Director of Engineering
Toronto Central Technical School

SAFETY VALVE AREA

The Editor,
"Power House,"

Dear Sir:

Having read the article in December 5th issue of Power House re "What should the Safety Valve Area Be" I think Mr. J. A. McGillivray is not applying the Canadian Interprovincial Safety Valve formulae correctly, because the boiler was not being operated under ordinary conditions (that is at normal capacity). Instead of using the formula

$$A = \frac{37.5\ G}{WP+15}$$

he should use the formula

$$A = \frac{W \times 0.22}{WP+.15}$$

for finding the area of the safety valve required as the boiler was being worked, or forced above normal rating during the test. In the latter formula

W = maximum number of pounds of water evaporated per hour
WP = Working pressure
A = area of valve required in sq. in.

Applying this formula to his figures

$$A = \frac{38700 \times 0.22}{200+15} = 40 \text{ sq. in.}$$

This area calls practically for 3-4½in. safety valves, because valves above 4½in. diameter are not allowed on high pressure boilers. The two 4½in. valves on the boiler are large enough if the boiler is not operated above 150% rating and too large for normal rating, because applying the formula

$$A = \frac{37.5 \times 110}{200+15} = 19.18 \text{ sq inches.}$$

This area requires 2-3½in. valves and two 3½in. valves have a relieving capacity of 22200 lbs. per hour and at normal rating the boiler would only require to evaporate $34.5 \times 600 = 20700$ lbs. of water per hour.

Applying the formula

$$A = \frac{W \times 0.22}{WP+15}$$

to his last problems, (If A=201 sq in.) to get an area equal to 201 sq. inches with this formula the boiler would have to evaporate 197600 lbs. of water per hour because

$$A = \frac{197600 \times 0.22}{200+15} = 202 \text{ sq. in.}$$

This area would require 13-4½in. valves because the area of a 4½in. valve= 15.90 sq. in. and $15.90 \times 13 = 206.70$ sq. inches which is close enough in this case. This formula shows that when A= 201 sq. inches, the boiler would have to develop about 5700 H. P. He states that only four 4 inch valves are required when A=201 sq. inches, because they have a circumference equal to the circumference of a 16in. diameter valve. This is wrong because A has nothing to do with the circumference of the valves, but only the area. If only four 4 inch valves were required A would have to equal only 50.26 sq. inches because the area of four inch valves equals that.

Yours Truly,
W. Tattersall,
Medicine Hat.

Flue Gas Filter

(Continued from page 35)

as with a horizontal return tubular boiler, the frame is omitted and the holder is bolted directly to the metal casing of the boiler.

Aside from the great gains in the reduction of attention required on the part of the attendant by the improved arrangement, another very important advantage results, namely that a smaller pipe line can be employed because its entire cross sectional area is effective when it is kept clean. Smaller pipe is not only easier and more economical to install but of even greater advantage, as it takes less time to draw a given volume of gas through it and consequently the CO_2 recorder reflects furnace operating conditions more promptly when smaller pipe is used.

While designed primarily for Uehling CO_2 equipment, "Pyroporus" filters may be used for other makes of instruments and the frames and holders are useful in connection with pyrometers, draft gauges and for providing convenient openings in the furnace for test and observation purposes.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

VARIOUS QUERIES

Question—If the throw of the eccentric is three inches what would be the valve travel and what would be the port opening?

Answer—The throw of the eccentric is half the valve travel, just as the throw of the crank is half the stroke of the engine. The travel of the valve must be equal to twice the lap plus twice the port opening. That is starting from midposition of the valve, in order to open the steam port at either end it would have to move a distance equal to the lap. In addition to this it would move a distance equal to the greatest port opening. The eccentric would then be at its dead centre, and starting to return. When the eccentric has made half its stroke the valve will be again in mid position and as the eccentric completes its stroke, the valve opens the port at opposite end to its full extent. Thus the throw of the eccentric is equal to the lap plus the port opening, and the travel is twice the throw so that the travel is equal to two laps and two port openings. We cannot tell the actual port opening without knowing the amount of lap.

Question—What is meant by the word phase in a motor?

Answer—In an alternating current machine the leads are taken from different parts of the armature, and the total current divided up between these leads. Thus in a three phase machine suppose the circumference of the armature to be divided in three parts, then three phases would be taken off 120 degrees apart from each other. In speaking of phase we also mean the relation of current and voltage to each other. Thus the electro motive force in an alternating machine may occur at the same moment as the maximum current in which case they would be in a phase, while if the maximum values occur at different periods in the revolution they are out of phase.

Question—What is meant by CO_2 and CO?

Answer—CO_2 is the chemical symbol for carbonic acid gas, or carbon dioxide, while CO is the symbol for carbon monoxide. CO_2 is the product of perfect combustion of carbon in conjunction with the correct amount of oxygen, while CO is the resulting product from imperfect combustion. The amount of CO_2 present in the flue gases determines the efficiency of combustion, and should be from 12½ to 16 per cent of the volume of the gases.

Question—How high will a column of mercury 28 inches high raise water in a pipe?

Answer—The weight of a cubic inch of mercury, that is one square inch area by one inch in height is .4908 lbs. A column of mercury thirty inches in height will just balance the pressure of the atmosphere, which is 14.7 lbs. per square inch. The pressure due to a column of mercury 28 inches high would be 28 x .49 lbs. per square inch, practically 14 lbs. per square inch. A column of water 2.305 feet high is equal to 1 lb. per square inch pressure, so that 14 lbs. per square inch will support a column of water 2.305 x 14 which is 32.27 feet.

Question—Draw a sketch of wire drawing?

Answer—Wire drawing is the term applied to the action of passing steam through a narrow orifice with the result that its pressure is decreased by the friction it has to overcome. In a diagram such as drawn by an indicator card, wire drawing would be shown by a swiftly sloping steam line.

Question—How does a condenser affect the steam and what gain is there in using a condenser?

Answer—When a condenser is used the exhaust steam instead of having to pass from the cylinder against atmospheric pressure, is passed into a vessel where it is either mixed with water and condensed, or passes over tubes and is condensed. As steam when condensed to water occupies only about 1-1600th part of the volume it occupies as steam, a vacuum is produced in the condenser. This means that the piston instead of having to work against a back pressure slightly above that of atmospheric pressure, has only to work against a back pressure of probably two to four lbs. absolute above vacuum. The engine is thus able to develop more power for the same steam consumption, or the same power for less consumption. The gain from condensing is in the neighborhood of 15 to 20 per cent.

Question—What would be the gain in raising feed water from 40F to 180F?

Answer—Every degree the feed water can be raised in temperature before going to the boiler leaves so much less heat to be added in the boiler. If this heat can be added from a source that would otherwise be lost there is a considerable economy resulting. As an approximation the saving of fuel is equal to 1 per cent. for every ten degrees the feed water is heated.

The following formula is more exact:

$$\frac{\text{Temperature leaving heater—Temperature entering heater}}{\text{Temperature of steam—Temperature entering heater plus latent heat}} \times 100$$

Question—What is the most dangerous thing to happen to a refrigerating machine?

Answer—Probably the most likely source of a serious accident would be the carrying over of large amounts of liquid to the suction side of the machine, which would have the same effect as water in a steam cylinder. This would be caused by passing more liquid through the expansion valve than could be evaporated by the surrounding medium, thus passing liquid instead of gas through the low pressure side of the system to the suction valve of the compressor.

SHOULD GAUGE GLASSES BE CLOSED

Question:—I am running a small plant and would like to know if there is any danger of the water glass breaking. It is a portable boiler used for heating purposes, 15 h.p. with the safety valve set to blow off at 15 pounds per square inch. It is without any attendance for about six to eight hours at night and I have found that it has made steam during that time with the bottom draft shut. Do you think it would be advisable to close the cocks on the water glass during that time?

Would you also tell me which way the check valves should be set on a high pressure return system from coils and where they should be located, as we have quite a bit of trouble with the steam trap. It lets a lot of steam pass through, although we had it fixed a short time ago. It is now as bad as ever through the cutting of the needle valve. Can anything be done to prevent this?

Would you tell me the best kind of check valve to use on the delivery pipe from injector to boiler and the location for best service.

Answer:—In leaving a boiler under banked fires and without attendance for any length of time, it is always advisable to close off the gauge glass cocks. The gauge glass is no use to anybody if they are not there to see it, and there

is always a possibility of it breaking. The result of a glass breaking and not being shut off will be to fill the engine room with steam, and if the banking of the fire has not been carefully done, the release of pressure due to the escape of steam through the glass will result in more water being evaporated, and there is a chance of the boiler being overheated directly over the banked fire. As long as the engineer starting up in the morning observes the usual precaution of blowing his glass through before touching the fire, there is little chance of the cocks being left closed while the boiler is working.

Without knowing anything of the system you have, it is impossible to say anything about the position of the checks. As regards the trap leaking through the needle valve, the only precaution to take to prevent this is to see that the valve is ground to a good substantial bearing in its seat, and that the valve spindle and the link it is fastened to, if any, allow it to come down to an absolutely even seat when working. If this is not done, a needle valve under high pressure will cut very rapidly.

We cannot through this column recommend any particular type of check valve, but we may say that the best check valve to use on a boiler feed line is the best that can be procured. The only way to make a selection is to become familiar with the different makes of valves, and their particular features of construction, and then use your own judgment.

AMERICAN METRIC ASSOCIATION

The above society are holding their annual convention in Toronto this week, concurrently with that of the American Association for the Advancement of Science. The Society has for its object the standardizing of the metric system in the United States, and has at present, bills before both Federal houses, containing legislation with this object. It is not sought to make any sudden change, but provdes for a period of ten years in which to adopt the new system. If this legislation does not pass, the Society will continue to work for the adoption of the system through its various connections with industrial firms and private persons. There is a similar Association in the United Kingdom, and a large number of distinguished men in both countres have given their approval to the object sought. Mr. W. M. Crocker is the secretary of the American Metric Society, and is at present in Toronto, The headquarters of the Society are at 156 Fifth Avenue, New York. Mr. Crocker has a large amount of literature bearing on the subject, which is an interesting one, and he will be very glad to furnish anyone interested in the matter with copies of the various papers. Mr. Theodore H. Miller, Works Manager of the De Laval Separator Co. will deliver a lecture during the convention on "Transition Engineering," in which he will give details of the experience of his company in adopting the metric system of measurements in their works.

CATALOGUES

Safety Switches and Panel Boards is the subject of catalogue 12-A, dated 1921-1922, which is now being distributed by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. This catalogue is profusely illustrated with views of installations of safety switches in the shop, in the office, and in the home. Dimensions and list prices of these switches are given in detail. Some of the subjects that are discussed are the railway type safety panel boards, the safety car lighting panels, the auto-lock control panels, the dead-front and dead-rear safety switchboards, the live-front knife switches and many other devices.

We have received from the Sterling Engine Co., Buffalo, their catalogue illustrating gas and gasoline engines for driving centrifugal pumps, for use in water works, industrial plants, and fire protection systems. Several of these units have been installed in Canadian cities. The catalogue is well illustrated and all the necessary information is included. Diagrams showing the space occupied by different sized installations are also given.

The Canadian Ingersoll Rand Co., Montreal, have issued in the form of a bulletin the paper on "Steam Condensing Plants," read before the Baltimore section A. S. M. E. in May last. The paper is a very interesting one, and contains much valuable information for those interested in the operation of this type of apparatus. Bulletins 1028, 1094, 9032, and 9224 covering low level and surface and Barometric condensers are now available and will be supplied to readers of Power House on request by the Canadian Ingersoll Rand Co.

Westinghouse Turbine Generator Units are described and illustrated in Circular 1094-B, just issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. This publication contains a discussion of the reactance and impulse types of turbines, both the semi-double flow type and the multiple cylinder type. Bleeder turbines and geared turbines are described, and each part of the turbine is elaborately treated.

The generator is also discussed in detail, and illustrations are given to show the latest types of construction.

The Combustion Engineering Corporation, New York, announce the opening of a new branch office at 806 First National Bank Building, Pittsburgh, Penn. This office will be in charge of Mr. C. W. Stripe, formerly manager of the Philadelphia office.

Laclede-Christy, St. Louis, have issued Bulletin No. 2, entitled, "Are Refractories Imposing a Limitation on Stoker Performance?" This bulletin discusses some of the features of refractory furnace linings, their use and abuse, and also the danger of selecting improper brick. It is well illustrated.

Industrial Works, Bay City, Michigan, is distributing free upon request Catalog No. 113, illustrating and describing the Type BC "Industrial" Crawling Tractor Crane of 20,000 pounds capacity.

This crane is pre-eminently adapted to the needs of road contractors, lumber and coal dealers, gravel, sand and stone producers, foundries, railroad reclamation and storage yards, and moderate-size manufacturing plants.

BRITISH CAPITAL AND CANADIAN INDUSTRIES

As a result of the recent visit to Canada of Mr. Ben H. Morgan, Chairman of Council of the British Empire Producers Organization, that body is now developing its Dominion industries service, particularly in interesting British capital in a number of Canadian industries. At the last meeting of council the matter was fully discussed and it was decided to invite any responsible Canadian bodies or individuals interested in such problems to communicate with the secretary of the organization at 3, Old Queen Street, London, S. W. I., England, with as full particulars as possible.

NEW FORM OF STAINLESS STEEL

The early forms of stainless steel were not such as could be easily worked, but a British firm of steel makers has been carrying on a series of experiments with a view to producing a steel which will retain rust resisting properties and can be worked without difficulty both in the hot and in the cold state. These experiments have been successful. The new plastic rustless steel can be stamped, punched, pressed, chased, or engraved cold; and it can be bent cold to a diameter equalling its own thickness without showing any signs of fracture. It may be polished silver bright, and this polish will remain in any atmosphere. In many cases a piece of this steel has less than half the weight of a brass or nickel piece of the same strength.

The Taylor and Arnold Engineering Co., have been appointed to act as dealers for the Davis-Bournonville Co., in Ontario, Quebec, New Brunswick, Nova Scotia and Newfoundland.

Mr. W. W. Avey, Norwich, Ontario, is in the market for engine, boiler and complete equipment for new planing mill.

Gropp Bros., Penetang, Ontario, are in the market for saw-mill machinery, boiler engine, belting, etc.

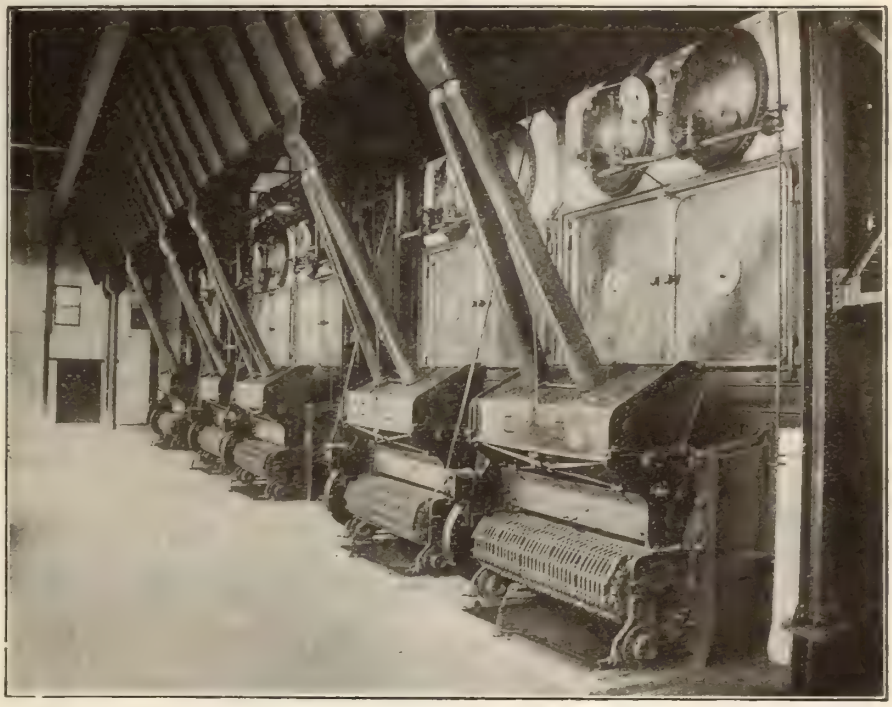
"B & W" *Marine and Land Type* Boilers

—Setting the World's Pace for Efficiency

All over the world, ashore or afloat; wherever there is steam used more than 20,000,000 H.P. of "B. & W." Boilers are taken as the standard of all that a boiler should be.

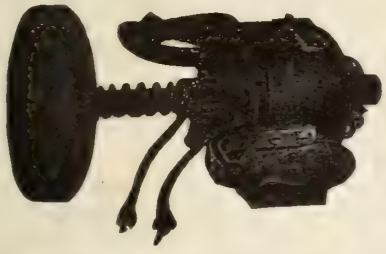
This leadership—indisputable leadership—is based on the three pre-eminent features of every "B. & W." Boiler. **Every "B. & W." Boiler is designed for the rapid, economical, and safe generation of steam up to the highest pressures!**

This degree of efficiency is attained through a construction devoid of all unequal strains—a construction which is easy to clean, easy to erect and of sufficient durability for many years of service.



Typical installation of "B. & W." Boilers with Mechanical Stokers.

Remove Scale from Tube Ends and Caps with the LAGONDA Reseating Machine



The "Lagonda" Reseating Machine, Motor Driven, Showing Emery Wheel.

When the **Lagonda Reseating Machine** is used tubes may be cleaned and caps replaced to headers with the assurance that steam and water tight joints will always result.

The **Lagonda Reseating Machine** consists of an emery or carborundum cloth wheel driven at high speed by an electric or water motor. It not only removes the obstructions but leaves the surface bright and polished so that the cap will fit perfectly.

To clean header faces the operator merely moves from tube to tube. To clean caps the machine is held in a vise. Machine is equipped with a guide ring which keeps wheel centered on tube.

Bulletin "G-1" shows the machine in use and explains its construction in detail. Write for copy.

"Lagonda" Boiler Tube Cleaners

For keeping the tubes free from scale. Water, Air or Steam Driven.

Boilers for 1922

Many a manufacturer could pay a dividend out of his coal pile if he went the right way about it. We mean that the very heart of his power plant—his Boilers—are inefficient, out of date, always longing for the repair man—and cost far more than they should in coal expense and labor.

Of course, because his Boilers are away down in the farther end of his plant, and he therefore rarely sees them, he doesn't know what fuel robbers and steam wasters they really are.

Our suggestion is—look into your Boiler situation now. You can get from us new, modern, absolutely efficient Boilers at exceptionally low cost that will be a delight to your staff and prove a very decisive factor in reducing your operating costs.

An Automatic Switch That Turns Lights Off Or On As Desired

A Number of Montreal Grocers Have Apparatus That Gives Them the Benefit of a Well-Lighted Store During the Hours of the Night When People Are on The Streets

MONTREAL.—A number of grocers and other merchants in this city have an apparatus in their store by which the light in either their windows or in the store itself may be turned off automatically during any hour of the night. This enables the grocer to leave his store at six o'clock with all the lights on and in this way getting full benefit of the display during the night when many people are on the street. He does not need to return to his store to turn off these lights so as not to be wasting electric power but this small apparatus will do the work for him at whatever hour he wishes.

Some of the merchants have had this apparatus made to order by local electricians. Others with a mechanical turn made it themselves. It consists of a small tin or galvanized iron box which stands about eight inches in height. An alarm clock is set in the box so that the face can be seen through a round opening in the front. The legs of the clock are firmly secured to the bottom of the box so that there is no chance for the clock to jump or move around when the alarm goes off. On the inside at the top of the box is placed a small switch to which the incoming and outgoing lines are attached as usual in an ordinary open switch. To the handle of the switch is attached a strong cord or in some cases a small metal rod which runs down to an extended arm which is attached to the winding key of the alarm. Then the alarm is set to go off at whatever time the merchant desires, usually 11 o'clock.

Works Accurately

When the alarm goes off the key that winds the spring begins to turn in the reverse direction. In doing this it brings the extended arm downwards which in turn pulls down the string or lever attached to the handle of the switch. In this operation the switch is released and the circuit broken.

As the little attached arm on the alarm key strikes the key on the main spring before it makes half a turn the spring on the alarm never gets a chance to become unwound. As a consequence the merchant never needs to re-wind the alarm. The next evening when he wishes to put in the switch for the lights in his store he gives the alarm key half a turn upwards an' puts the switch in. The clock is once again ready to release the switch when the desired hour comes.

Merchants who have the apparatus in their store claim that it is quite inexpensive to make and a number of them have made quite satisfactory clock-switches themselves. Nothing needs to be said with regard to the advantage of such a switch for every merchant will realize the advertising value of having his store lighted during the night even though he has his store locked up.

In making this apparatus one precaution should be taken and that is that the inlet or the incoming current should come from the top of the box so that when the switch is pulled out there is no danger of a short circuit being caused by the arms of the switch coming in contact with the metal of the clock. When the current enters from the top of the box the arms of the switch are quite "dead" when the switch is pulled out.

$50 Worth of Books for $3

Fifteen of the Best Sellers of the Year For $3 if you subscribe to MacLean's Magazine

During 1921 MACLEAN'S, Canada's National Magazine, has published the whole or major portion of the following fifteen books, which have since been published in book form—or are shortly to be published:

(1) Reminiscences of a Raconteur
—Col. George H. Ham
The recollections of Canada's premier story teller, the C.P.R.'s knight of wit and wisdom, who has known every person worth knowing in Canada during the past half century.

(2) Masques of Ottawa—"Domino"
A series of brilliant, biographical sketches of Canadians prominent in politics and business; analogous to "The Mirrors of Downing Street."

(3) Canada at the Cross-Roads
—Agnes C. Laut
A series of vigorous, inspirational articles showing how Canada is standing on the threshold of nationhood; constructive criticism indicating how full national status is being achieved.

(4) Policing the Plains
—Rev. R. G. MacBeth
The latest and most authoritative history of the Royal North West Mounted Police, by a padre who himself took part in the Riel Rebellion and has associated with many of the leading characters in Canada's famous frontier force.

(5) The Drama of Our Great Forests
—Arthur Heming
The pulsating, throbbing, human-interest story of Canada's great northern fastnesses, told by the man who will go five hundred miles to get a fact; authentic, enthralling.

(6) The City of Peril—Arthur Stringer
An up-to-date narrative of a Bolshevistic plot which was nipped in the bud by an adventurous young millionaire; including a delightful Stringer-like romance.

(7) Pawned—Frank Packard
A fast-moving story of a triple regeneration, shifting wth kaleidoscopic speed from the South Sea Islands to this continent—novel, intense, gripping, mystifying.

(8) The Valley of Gold—David Howarth
The first novel from the pen of an athletic Methodist parson now resident in Miami, Manitoba—a true-to-life account of the Qu'Appelle Valley of Saskatchewan as it was twenty years ago; vigorously, thoroughly Canadian.

(9) Mostly Sally
—Pelham Grenville Wodehouse
A worthy successor to "The Little Warrior," told in the inimitably facetious and whimsical vein of this English master-craftsman.

(10) The Yellow Streak
—Valentine Williams
The story of a murder mystery solved by real human beings; from the pen of the author who wrote "The Man With the Club Foot."

(11) The Gates of Tien T'ze
—Leslie Howard Gordon
An enthralling book which ran in MACLEAN'S as a five-part serial; dealing with life in London when Anglo-Saxons and Chinese met at cross purposes.

(12) Lenix Ballister, Diplomat
—Archie McKishnie
A dozen short stories about the typical Canadian negro of Western Ontario; a forthcoming volume from the pen of one of Canada's foremost fiction writers.

(13) Prince Renine—Maurice Le Blanc
Eight more stories in which the leading character is the thinly disguised Arsene Lupin, one of the world's famous characters in detective fiction.

(14) A Series of Short Stories
—"Sapper"—H. C. McNeile
Ten or a dozen brilliantly written stories, impregnated with human interest, from the pen of one of the most successful English authors brought to the fore during the war.

(15) The Man Who Knew Too Much
—G. K. Chesterton
A collection of eight stories, each with its distinctive mystery, and containing the usual Chestertonian twist, from the pen of the man who wrote the "Father Brown" series.

Readers of MACLEAN'S got all these books in 1921—ten books of fiction and five of a more serious character, biographical, reminiscent, political—permanent literature.

In addition, they got a most attractive offering of the best short stories and the twice-a-month Review of Reviews department, which kept them posted on current topics and developments in all parts of the world, as well as the multitude of Special Articles on Topics of National Interest in Canada, which have made MACLEAN'S something more than a magazine—a National Institution.

MACLEAN'S readers got all this immense value in 1921—in 1922 they will get bigger value still. And you get all this for $3.00—the price of a year's subscription—24 twice-a-month issues of

Saves When You Use

Time is a big item of cost in testing gauges. With an American Dead-Weight Gauge Tester you can test three or four gauges in the time ordinarily required to test one with most other instruments. This is partly because you can hold the pressure at any point as long as desired, thus making it quick and easy to take accurate comparisons of the gauge reading at any point on the dial with an

AMERICAN DEAD WEIGHT GAUGE TESTER

Another time-saving feature is in the fact that the American is the only completely self-contained tester on the market.

In addition to saving minutes and therefore saving money every time it is used, the American also saves money in the long run, for its rugged construction means long life. It is lighter, less bulky and therefore handier to carry around than most testers.

Made in various sizes for pressures from 5 lbs. up to 1000 lbs. Other equally efficient types for higher pressures.

Our interesting Gauge Tester Circular sent on request.

Know What You're Doing

Power plant records tell the efficiency of the plant to-day and furnish a means of comparison with the results obtained a day, a month, or a year back. The

VENTURI METER

by indicating, registering and recording the rate of flow to the boiler reveals immediately any condition detrimental to economical boiler operation and furnishes an indelible record of its import and duration.

Bulletin 197 lists in detail the advantages which may be derived from VENTURI METER records, and will be sent on request.

The VENTURI measures hot and cold water, sewage, brine, chemical solutions, oil, gas, air and steam.

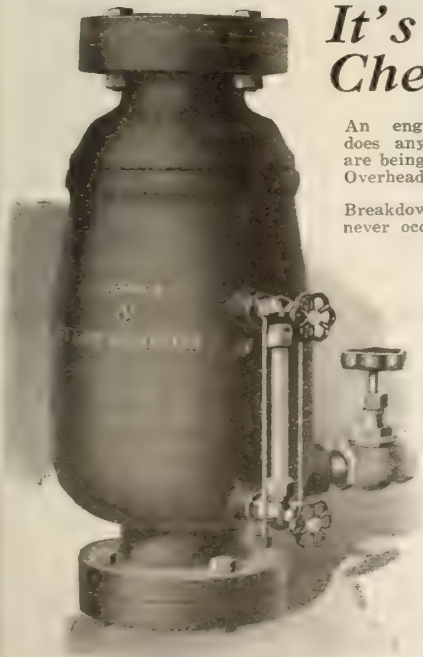
Use Quality Steam!



It's the Cheapest.

An engine breakdown never does anybody any good. Men are being paid for standing idle. Overhead is piling up.

Breakdowns of this nature need never occur. They can be prevented by supplying quality steam — steam that is hot and dry.

The ANDERSON STEAM SEPARATOR is scientifically designed to remove the greatest amount of moisture practicable with a separator. It thoroughly separates the moisture so that it cannot be picked up again. Built of the best materials — thoroughly tested and inspected in our factory before being shipped.

Write for a copy of our Steam Specialty catalogue.

West 96th St., Cleveland, Ohio

If Your Fireman

Were Made Manager

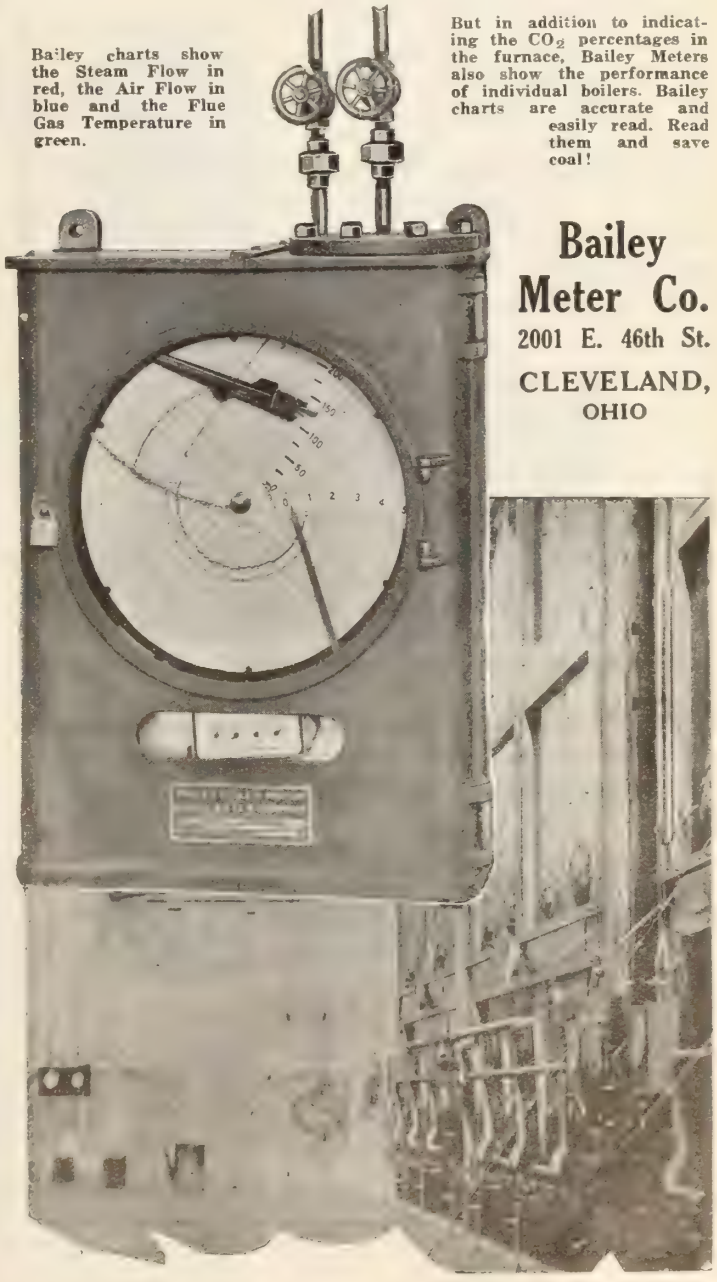
Possibly his first move would be the installing of

BAILEY BOILER METERS

Because being a practical man he would want to take every precaution to safeguard his plant against the coal wastes that are bound to occur where no checking system is employed. He knows that dirty flues, dirty grates, etc., mean wasted coal. Bailey Meters show when these things happen.

Bailey charts show the Steam Flow in red, the Air Flow in blue and the Flue Gas Temperature in green.

But in addition to indicating the CO_2 percentages in the furnace, Bailey Meters also show the performance of individual boilers. Bailey charts are accurate and easily read. Read them and save coal!



Bailey Meter Co.

2001 E. 46th St.

CLEVELAND, OHIO

HINTS TO BUYERS

Kingsbury Thrust Bearings

Made in Canada

Our pivoted-block Thrust Bearings are a complete solution of all thrust-bearing problems in hydro-electric units, steam turbines, ships' propeller shafts, centrifugal pumps, and similar work involving heavy loads and high or low speed.

Maximum Durability and Reliability.
Lowest possible Friction.
No limit to loads or speeds.

Protected by numerous Canadian Patents. Complete manufacturing facilities in Canada, insuring prompt deliveries and service.

Send for Catalogue.

Hundreds of Tons of Coal Are Destroyed Every Year by Men!

LABRIDE COAL Handling Equipment

Protects coal from the ravages of Pick and Shovel

LABRIDE EQUIPMENT consists of a moving bridge traveling lengthwise of the storage space and a bucket trolley travelling crosswise on the bridge.

Every square foot of storage space is covered with a minimum of movements and time. Capacity from 60 to 90 tons per hour. Write or wire for particulars.

LAKESIDE BRIDGE & STEEL COMPANY, 159 Villard Ave., NORTH MILWAUKEE, Wis.

New Truths and Old Fallacies

Atomic Volume, etc.--*Continued*

Despite the fact that impurities of low atomic volume are injurious to a babbitt alloy, some manufacturers seem quite oblivious of it, as they give wide publicity to the fact that their alloys contain such impurities, even incorporating them in the name of their products as an attractive feature to secure confidence and business.

If, in the future, such compositions are not featured so prominently, it can be judged from whence comes the reformation.

The presence of oxide in an alloy is equally harmful, as it cannot be reduced to a metallic state by the ordinary process of compounding in an open kettle, and, therefore, its exclusion is important.

GRIT AND DUST

A valuable feature of Magnolia Metal, not previously mentioned in this article, is its immunity from the generally harmful effects of grit and dust. Under such conditions, Genuine Babbitt and bronze and brass bearings heat and wear rapidly and are prone to score and seize, but in the case of Magnolia, these fine particles of grit become embedded in the matrix and covered over by it, so that harmful effects are neutralized. Because of this noticeable Magnolia feature, it is used extensively in cement, plaster, sand drying, grinding, buffing, rock crushing and other similar machinery bearings. This desirable feature has also been commented upon by steamship engineers in relation to propeller shaft bearings which are subjected to ashes in the bilge water.

Thousands of Dollars are Being Wasted

By Inefficient Handling Methods

Industry must be revived, but only the fittest in it will survive. Competition will be extremely keen. Only those who eliminate wasteful processes and inefficient methods will get ahead. How about you? Have you installed cranes to handle your supplies and do your heavy lifting? No—Then send us a plan of your shop, giving the width, height, headroom, and loads to be lifted. We will advise you what to do.

HEPBURN Hand Overhead Crane

Built with Single or Double 1-Beams, in sizes from ¼ to 20-ton capacity.
We also make Pumps, Vertical Engines, Compressors, Castings and Forgings.

An Expensive Tool

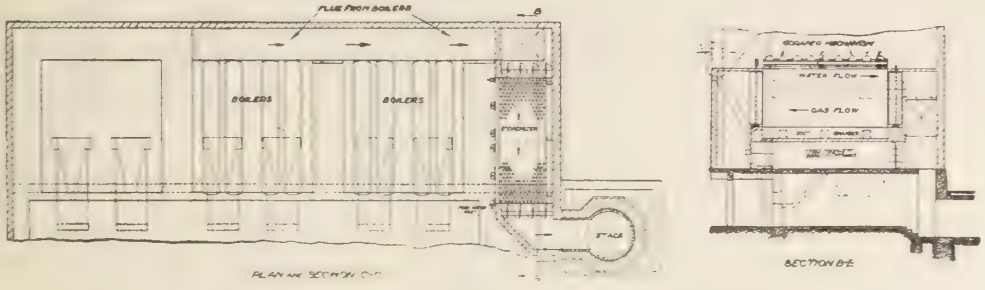
Every shovel of coal costs money { at the mine / at your plant / on your grates

Every shovel of ash costs money to remove.

Sturtevant Fuel Economizers, by heating the boiler feed water, utilize the heat which is wasted up the stack.

Every 10 degrees rise in feed water temperature means 1 per cent less { coal to shovel / ash to remove / freight to pay

What does this mean on your coal bill?



A Typical Sturtevant Fuel Economizer Layout

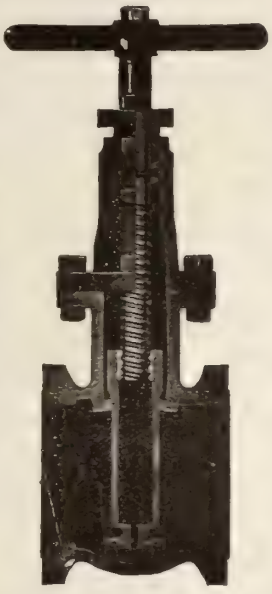
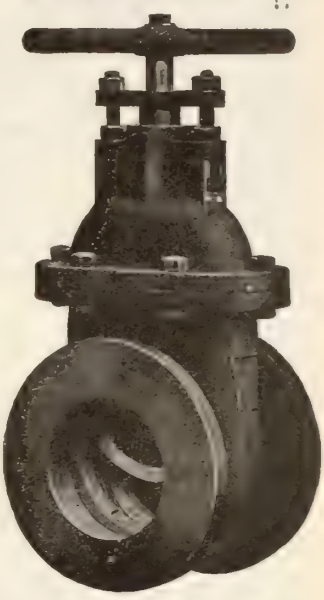
KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

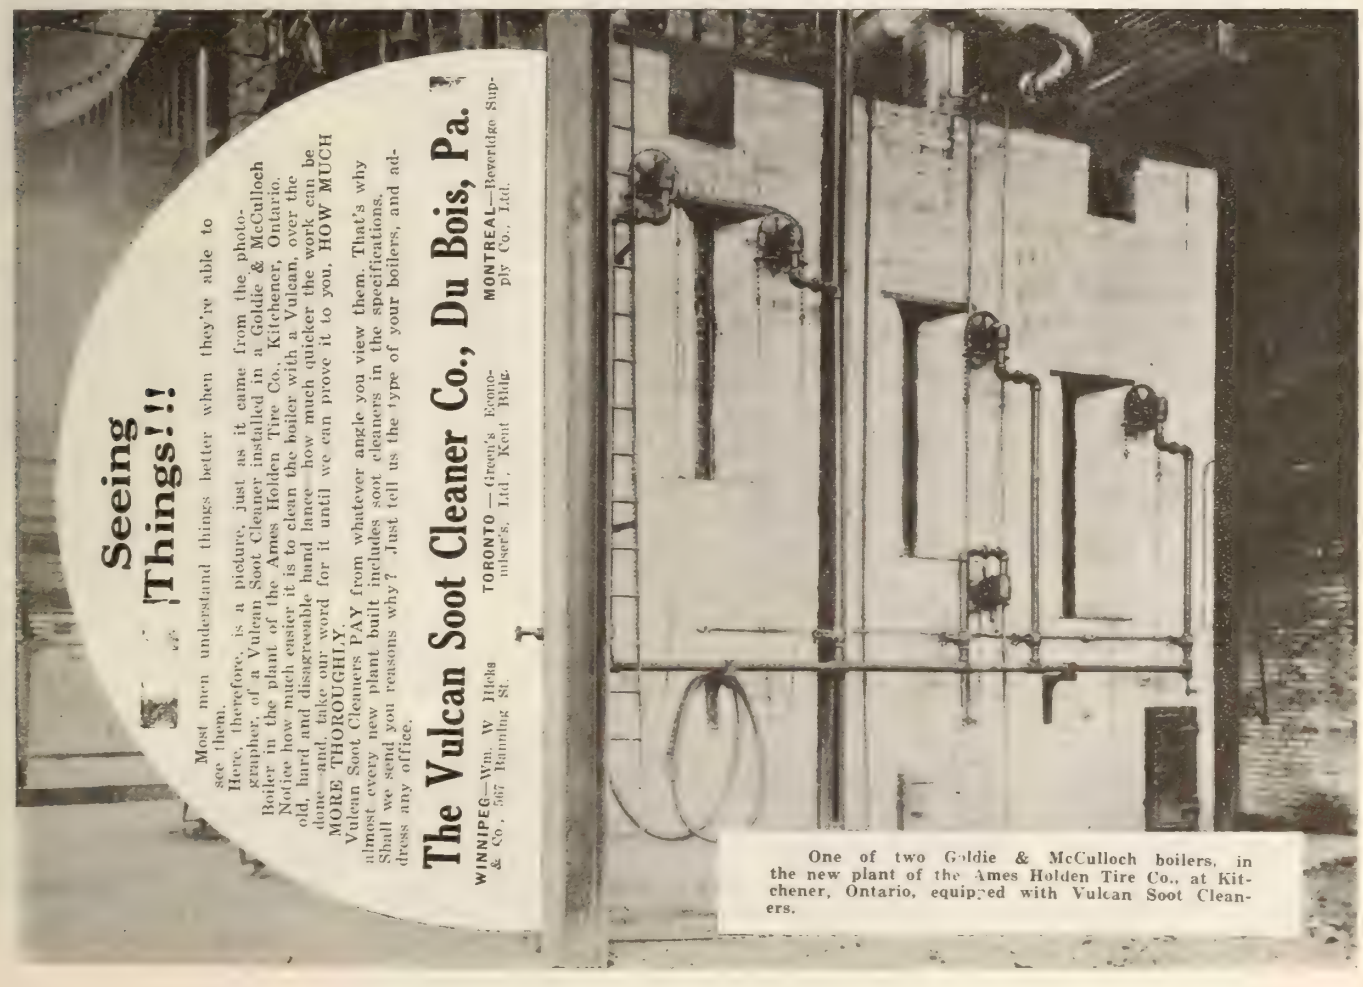


If you have been using them, we are confident that our satisfaction will bring us your repeat orders These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**



Seeing Things!!!

Most men understand things better when they've able to see them.

Here, therefore, is a picture, just as it came from the photographer, of a Vulcan Soot Cleaner installed in a Goldie & McCulloch Boiler in the plant of the Ames Holden Tire Co., Kitchener, Ontario.

Notice how much easier it is to clean the boiler with a Vulcan, over the old, hard and disagreeable hand lance—how much quicker the work can be done—and take our word for it until we can prove it to you, HOW MUCH MORE THOROUGHLY.

Vulcan Soot Cleaners PAY from whatever angle you view them. That's why almost every new plant built includes soot cleaners in the specifications. Shall we send you reasons why? Just tell us the type of your boilers, and address any office.

The Vulcan Soot Cleaner Co., Du Bois, Pa.

WINNIPEG—Wm. W Hicks & Co., 567 Banning St.

TORONTO — Greey's Economisers, Ltd., Kent Bldg.

MONTREAL—Beveridge Supply Co., Ltd.

One of two Goldie & McCulloch boilers, in the new plant of the Ames Holden Tire Co., at Kitchener, Ontario, equipped with Vulcan Soot Cleaners.

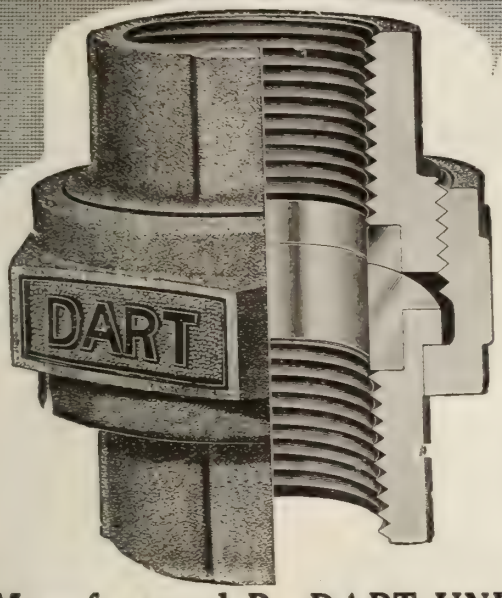
"DART" UNIONS

WILL NOT LEAK

BECAUSE

The Bronze Face and Seat will last indefinitely—there is no rusting or corroding at the joint, no deterioration.



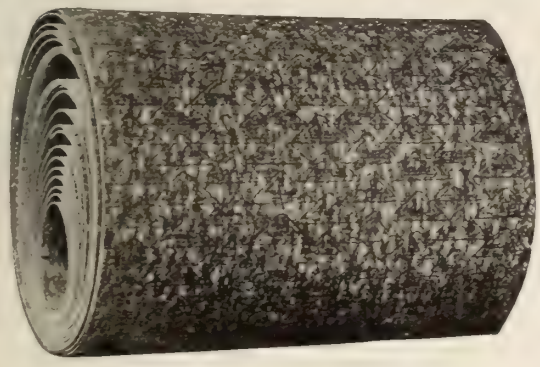
There is something more than metal in every "Dart" Union, accurate workmanship, true threads both as regards taper and pitch, clean cut, and strong where the strength is needed. Every union fault has been eliminated from Dart Union pipe couplings.

It Pays to think "DART" When Ordering Unions

Manufactured By DART UNION COMPANY, LIMITED, TORONTO, ONT.

Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.



Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

Stock Sizes

36 in. wide x 144 in. long.

48 in. wide x 144 in. long.

In thicknesses of 1-64 1-32, 1-16, 3-32, 1-8

Let us send you a trial order.

ELESCO

SUPERHEATERS
ARE MADE IN CANADA

Elesco Superheater Installation in Stirling Type Boiler.
Header and units are arranged for easy accessibility outside the boiler setting. There are no joints inside the boiler.

Don't Spend More Than You Have To For Additional Power

As your plant grows you will need more power.

How are you going to get it?

New boilers and settings are expensive. Will your boiler house take them? A power house extension, or a new power house, will require money that should go into production equipment.

One rapidly growing plant has met former demands for greater power by installing Elesco Superheaters. But more power is needed now. The two remaining saturated boilers will also be equipped with Elesco Superheaters, to give the boiler capacity desired, and save the cost of new boilers, their installation, maintenance and operation.

Elesco Superheaters increase existing boiler capacity from 10 to 20 per cent at about one-fifth the cost of obtaining an equal increase by the installation of more boilers. May we send you the details?

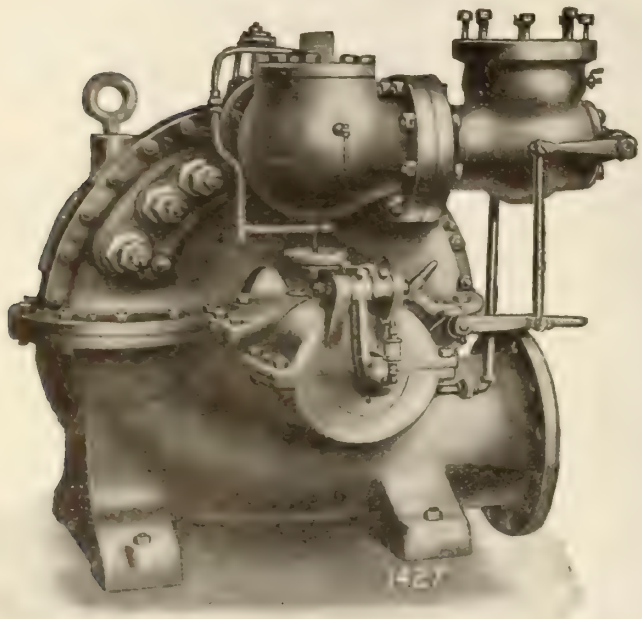
Keep High-Temperature Steam Away From Bearings



THE new DE LAVAL VELOCITY-STAGE TURBINE meets the requirements of modern steam plants using high pressure superheated steam. The cast-steel steam chest is in the upper part of the casing, away from the bearings and their supports. Only low-pressure, low-temperature steam enters the wheel chamber. Hand-controlled nozzles provide for maintaining efficiency with varying load and steam pressure. The speed is controlled by a powerful and accurate governor, besides which there is an entirely independent emergency trip with shut-off valve.
De Laval Steam Turbines are built on a limit-gage, interchangeable basis in all sizes up to 15,000 H.P. and for all steam conditions.

Ask for Catalogue T-100.

This Mark On Belting

Means the End of Your Belt Troubles

BRITISH OAK TANNING

D. K. McLaren's Belting is tanned by this world famous process—a process which eliminates stretch, adds strength and flexibility yet retains all the hide's natural strength.

PERHAPS you smile confidently and say: "Why, I have no belt troubles." If so you are indeed fortunate. Do you know that every day while the busy executive is striving to find a means to keep overhead down, an improperly selected belting is actually piling up overhead? And the worst part of it is that it is sometimes hard to tell the difference between a good belt and a poor one.

The sure sign of power saved is the Oak Leaf—stamped on all D. K. McLaren's Genuine British Oak Tanned Leather Belts. Every D. K. McLaren Belt is made from the flawless backs of choicest steers; tanned until it becomes tough, durable, and practically stretchless. Every D. K. McLaren Belt represents big economy by giving long power-saving service.

Fill in your name and address, tear out and mail the attached coupon to our nearest branch today.

Carrying High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

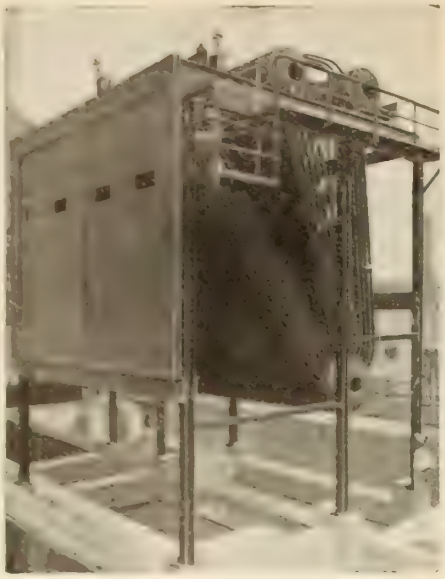
They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.

The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.

Write for full particulars on the Files now.

Waterous

BRANTFORD, ONTARIO, CANADA



Connelly Water Tube Boilers

are of the 4-drum type; have 100% tube area in the path of circulation, and deliver steam superheated to from 5 degrees to 10 degrees Fahrenheit. Simple in design, no flat surfaces, no stay bolts, no crown bars, no braces, no handholes, free from joints.

All parts easily accessible for cleaning, both internally and externally. Can be built in units from 200 H. P. up to 4,000 H.P. and for working pressures up to 300 lbs. per sq. in. Over 150,000 H.P. in successful operation.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Turbine-Driven Blowers
Must be Rugged

THE DE LAVAL TURBINE-DRIVEN BLOWER unit shown is designed for gas plant work. It serves however, to illustrate the care taken in designing De Laval apparatus to insure continuous, satisfactory service. Note the heavy construction of all parts, including the blower casing, also the forced lubrication with sight feed and the powerful and accurate speed governor, all features contributing to reliability in operation.

The same features are apparent in the design of all other De Laval apparatus, including turbine-driven generators, centrifugal pumps, blowers and compressors, speed-reducing gears, geared turbines for rope and belt drive, etc.

State class of apparatus in which you are interested and appropriate literature with special data will be supplied. Ask for Catalog F100.

LUNKENHEIMER
Cast Steel Valves

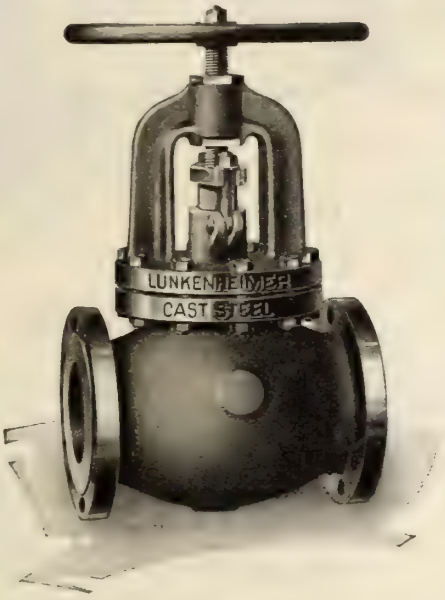

Fig. 606

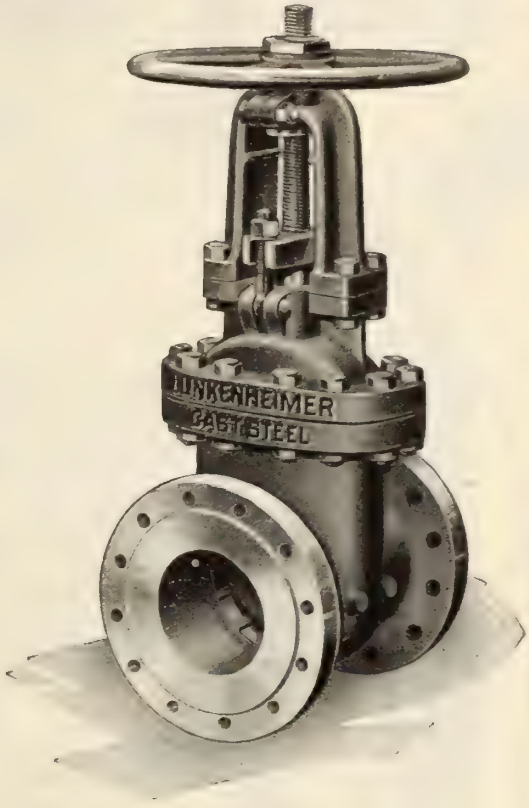

Fig. 1353

For power plants where high pressures and more particularly excessive temperatures prevail. The 800° F. temperature and 350 pounds pressure rating for which LUNKENHEIMER CAST STEEL VALVES are guaranteed covers every requirement of modern practice and provides a margin of safety which insures both efficiency and maintenance economy.

Lunkenheimer "Valve-steel" is melted by the electric process exclusively, with definite regulation of each step in the foundry. This method provides a metal structure both homogeneous and free from casting defects and highly suitable for valve service. The trimmings are monel.

The line is complete and includes Globe, Angle, Check, Gate, Non-return, Pop Safety and Blow-off types in all standard sizes.

Specify LUNKENHEIMER CAST STEEL VALVES and insist on their installation. Distributors of Lunkenheimer Products situated in every commercial center. Write for catalog No. 58-D.C.

Are you interested in any of these fields—power—metal working —marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric. Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)

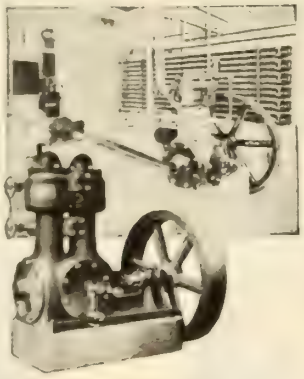
A YORK MACHINE

does not require a skilled operator



DON'T get the impression that Mechanical Refrigeration means complicated apparatus, difficult to understand and costly to operate. You need have no such fears if it's a YORK installation.

A York plant is the embodiment of simple efficiency. No skilled attendant is required. One of our customers says in testifying to the simplicity of his York plant, "It is being operated successfully by an employee who, prior to the installation of the machine, had never seen one nor had any experience in operating one."

Constant attention is unnecessary. The simple regulation of one valve gives any degree of cold you want—freezing, zero, below zero—whatever your business needs may require.

If you want the simplest, most efficient, most economical refrigerating system, you will investigate the York Refrigerating Plant.

P&H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

SCREWED FLANGES.—For general service, our screwed-on flange gives universal satisfaction and is the least expensive. For steam and water lines, at pressures up to 125 lbs. the flange is screwed home and not refaced. For higher pressure, we recommend screwing on the flange until the end of the pipe projects beyond the face, then refacing by taking a cut across the flange and end of pipe, insuring a perfect joint with the gasket bearing on the end of the pipe. This prevents the pressure from working through the thread of the flange, and insures a long life for the joint.

For all High Pressure service, and where it is objectionable to reduce the thickness of the wall of the pipe by threading, we recommend P&H Lap Joint.

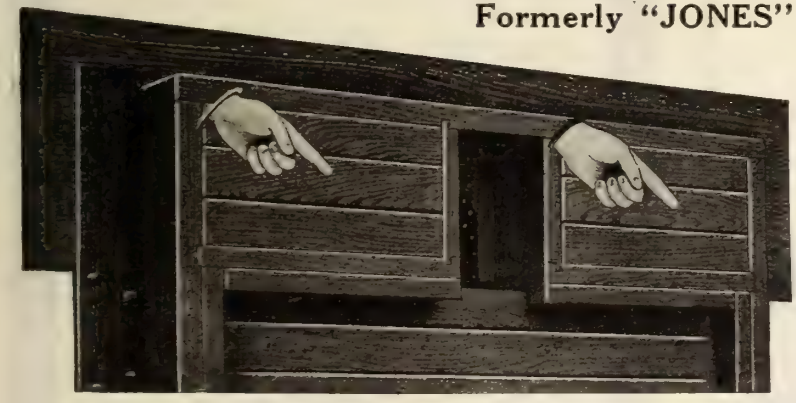
Incomparable JAMISON

Formerly "JONES"

Heavy Duty Cold Storage Doors



Have Many Points of Superior Construction

Note the back of our Standard Track Head Frame with track part; we insulate and finish our track frame heads, an unusual feature. Then note the simplicity of the Track Lift device over the door; no springs or other delicate parts to get out of order. Our Automatic Self-tightening Fastener draws the door rigidly tight each time it is slammed. The hinges too are three to five times heavier than other makes.

These features, and many others, are fully explained in catalog No. 10. Write for it.

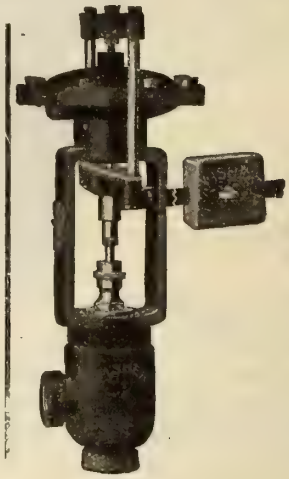
FISHER

TRADE MARK REGISTERED



Perfect Control of Vacuum Pumps

If you are using a Steam-Driven Vacuum Pump for any purpose in your plant you will want the

Fisher Vacuum Pump Governor

(Type 8)

It is a thoroughly reliable regulator that will accurately maintain any desired vacuum.

The reliability of this governor has been established by its extensive use. It has been adopted as standard equipment by some of the largest manufacturers of vacuum pumps and installers of heating apparatus in the country.

Its construction is such that all unnecessary friction is eliminated. The large controlling diaphragm makes it extra sensitive. Lever and weight control is positive, and we can furnish this valve in either angle or globe type—a great convenience on many installations.

Our book, "POWER PLANT SPECIALTIES," contains valuable information to engineers. Write for your copy to-day. Fisher Power Plant Specialties can be ordered through jobbers anywhere in Canada.

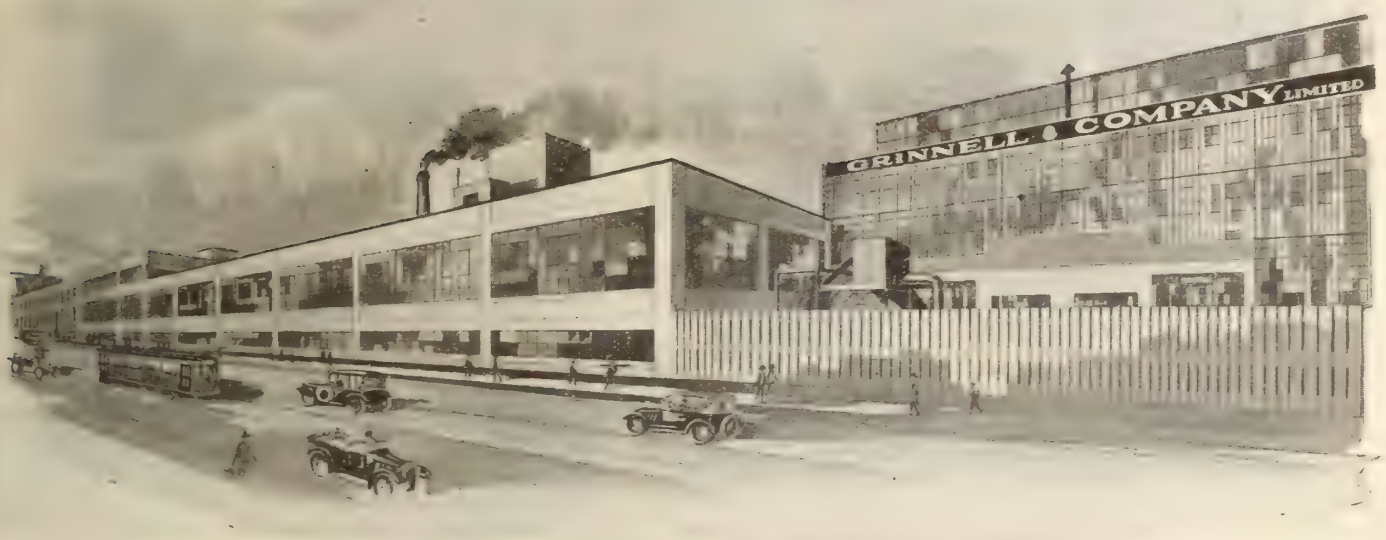
Jenkins Valves



THE GRINNELL COMPANY'S PLANT AT TORONTO, ONTARIO

The Grinnell Plant At Toronto Is Equipped With Jenkins Valves

Fig. 300

Like many other manufacturers with big production and wide distribution the Grinnell people fully appreciate the importance of dependable valve equipment.

Naturally when it was a question of dependability they chose Jenkins —the Valves with the Diamond Trade Mark.

Hence Jenkins Valves, through the efficient and trouble-free service they render, are playing an important part in the production of the well-known Grinnell Sprinkler Systems.

Jenkins Valves are made in types and sizes for every service everywhere. They can be installed with confidence to furnish maximum service and to function satisfactorily under unusual conditions and hard usage.

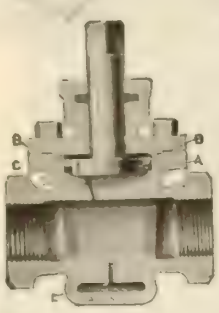
HOMESTEAD
Quarter-Turn Valves

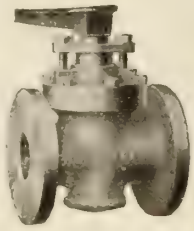


Why they can't be otherwise than tight

They are **seatless!** They are not subject to the cutting and scoring which affects the seating surfaces of globe and gate valves.

Tightness is further insured by a patented wedging cam that automatically forces the plug downward in action and again instantly releases it.

A single quarter-turn operates a Homestead. That's why they are preferred to time-wasting, money-consuming globe and gate types.



May we send you a copy of our latest catalogue?

John Crane

Eight Years of Packing Service
JOHN CRANE Flexible Metallic Packing Shows Greatest Results in Constant Service

Eight years ago Chief Engineer, N. Gross, of the Standard Oil Building, Chicago, installed JOHN CRANE Flexible Metallic Packing in the boiler-feed pump pictured below. Mr. Gross reports packing and pump in good order after eight years and has standardized JOHN CRANE on all service.

JOHN CRANE holds this long service record because of its scientific, practical construction. Made of babbitt foil and graphite, it brings Packing science "The Babbitt-bearing Principle," and while responding to the slightest pressure of the gland never dries out, but remains compressible and will not score rods.

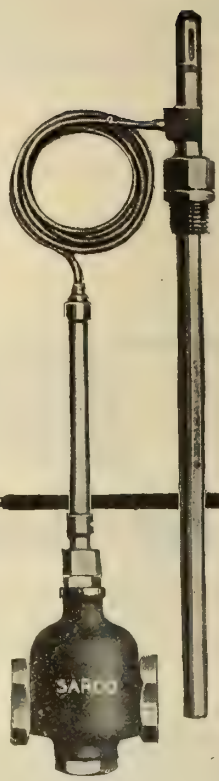
SARCO

Temperature Regulator is a Tireless Watchman



It keeps the temperature uniform in your apparatus. From morning 'til night, day in and day out, it steadily maintains the right degree of heat no matter how delicate the process or how trying the conditions under which it works.

At the same time it eliminates spoilage of costly materials due to fluctuating temperatures, and saves valuable time that is otherwise wasted by juggling the crude hand valve as a means of temperature control.

Furthermore, the Sarco demands no wages, observes no clock, and is never subject to exhaustion or breakdown because of unwavering attention to work and watching the temperature.

But best of all, the foreman need give a Sarco Regulator no other attention than a slight adjustment—after which it may be entirely forgotten. You can be sure its highly sensitive and absolutely dependable action will regulate temperature so precisely that at no time during the process will fluctuations be permitted to exist.

And it is so easy and convenient to employ one of these workers for every heating unit you have in your plant. Simply send for a Sarco on trial. It stays for 30 days without cost or obligation, and if it fails to do your bidding, all you need do is to send it back post haste. The trial costs you nothing whatever.

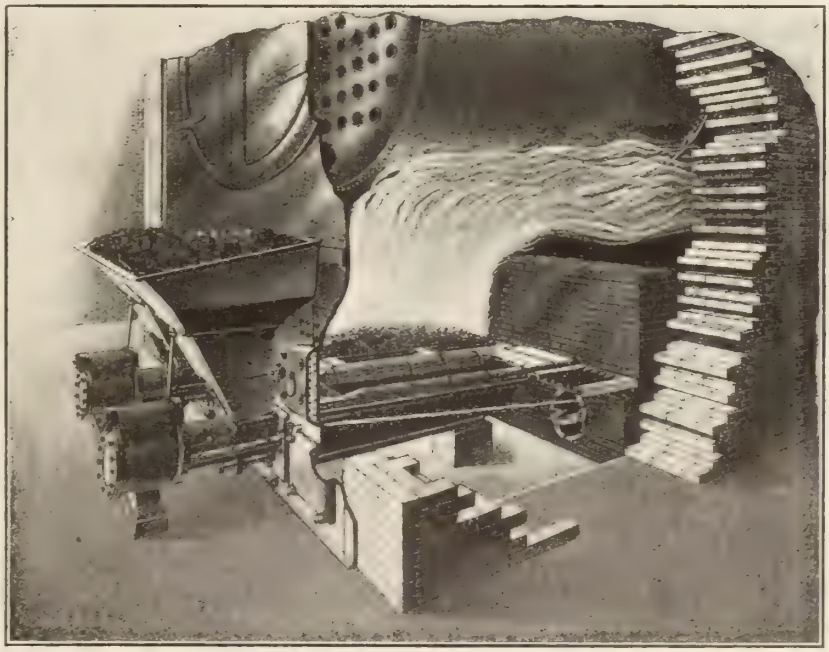
THE
MACLEAN
UNDERFEED STOKER

The Biggest Cost-Cutter in the Plant

The MACLEAN STOKER saves coal and saves labor. It automatically feeds the fire just the right amount of coal at the right time. As a result constant steam pressure is carried regardless of varying loads on the boilers. Every plant, large or small, needs a MacLean Stoker. It responds to sudden demands for steam and maintains a smokeless chimney even when using low grades of coal. It is easy to operate, easy to instal, clean tubes and heating surfaces due to clear combustion. Small cost of upkeep because no moving parts are in contact with the fire.



These and other features enable the MACLEAN STOKER to pay for its installation in a surprisingly short time. Write us and we'll tell you how.

MacLean Underfeed Stoker Company, Limited
95-97 KING STREET EAST, TORONTO, CANADA

Jones

—a type for every plant

THE most important of all power plant problems is the correct burning of coal. In the larger central station, coal constitutes 40% of the total cost of operation. In the average boiler room itself 80% of the total expense is found in this one item.

There is a Jones Stoker for every requirement regardless of the size of the plant or the boiler, the nature of the fuel or the range of the load—whether the plant is old or new. Jones Stokers are also extensively used in various industries for chemical, metallurgical and enameling furnaces, in fact, wherever efficiency, control of heat and smokeless operation are desired.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co. of America are made available for Canadian power users. Thus this strictly Canadian stoker is backed by world-wide experience and unequalled engineering ability.

All Jones Stokers are characterized by unmatched simplicity, sturdy construction, and therefore by lower maintenance costs. They consist of one or more simple self-contained retorts with one moving unit, and no moving parts in the fire.

All embody the highest development of the underfeed principle of combustion—originated and perfected in the Jones Stoker. More economy in fuel burning is thus assured with ability to burn all Canadian coals smokelessly.

Every type of Jones Stokers is provided with automatic control of fuel and air, which insures efficiency at all rates of operation. Where stokers are applied to boilers an even steam pressure is automatically maintained. Where applied to industrial furnaces, both the quality and quantity of the heat is controlled.

How can you know which type you need? Read the description of the Jones series.

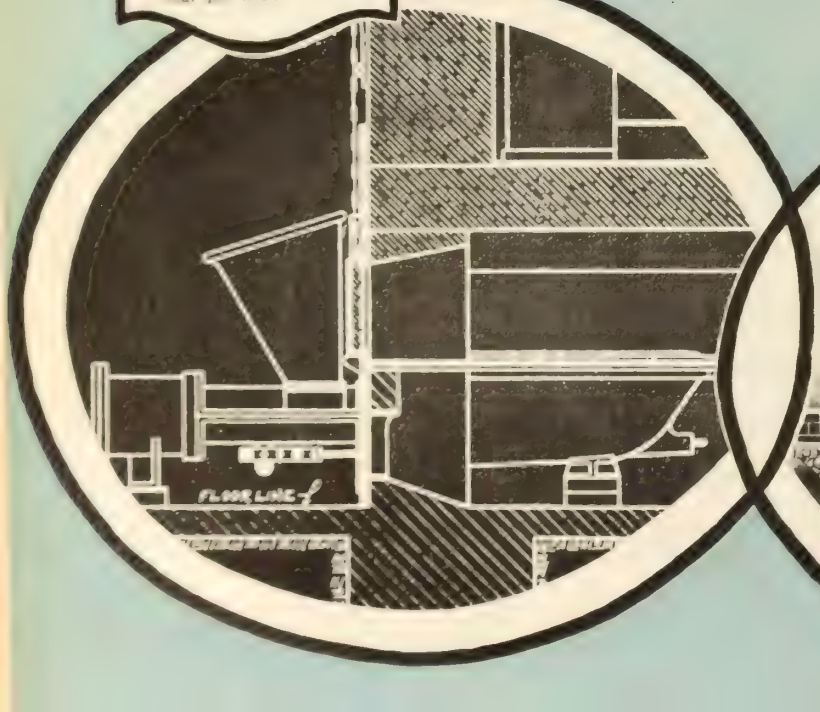
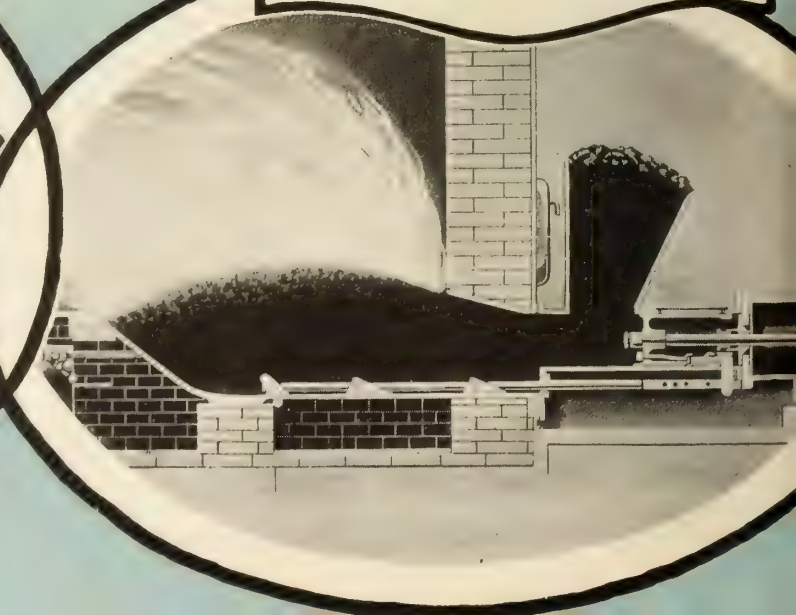
"Light-Duty"

—a small but highly efficient and entirely automatic stoker for use with metallurgical furnaces, chemical processes and smaller boilers. Inexpensive to install. Requires minimum attention. This stoker has a fuel burning capacity of from 60 to 200 lbs. of coal per hour.

"Standard"

—a stoker that embodies the basic Jones features. Moderate in first cost. No special excavation required for ash pit. Simplest underfeed stoker. There are more Jones "Standard" Stokers under Return Tubular Boilers than all other makes of stokers combined. The "Standard" Stoker is widely used for industrial heating furnaces. This stoker has a fuel burning capacity of 1,000 to 1,200 pounds of coal per hour. Single units serve boilers up to 200 H.P.

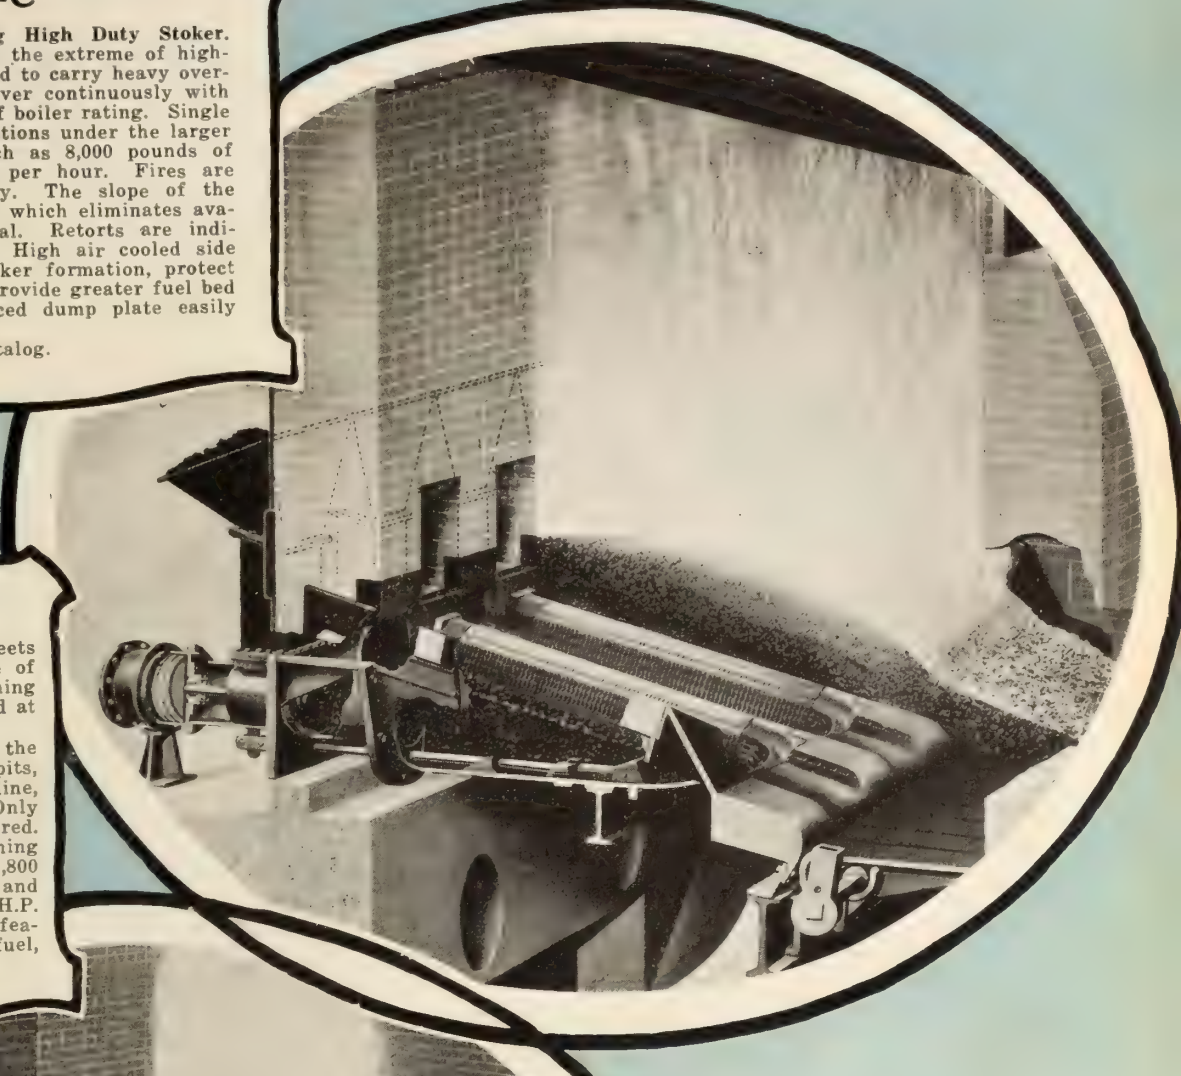




Stokers

"A-C"

— **Automatic-Cleaning High Duty Stoker.** A stoker for meeting the extreme of high-duty service—designed to carry heavy overloads of 200% and over continuously with peak loads of 300% of boiler rating. Single "A-C" Stoker installations under the larger boilers burn as much as 8,000 pounds of coal to each boiler per hour. Fires are cleaned automatically. The slope of the fuel bed is only 11°, which eliminates avalanching of live coal. Retorts are individually controlled. High air cooled side tuyeres prevent clinker formation, protect side walls and also provide greater fuel bed area; simple, balanced dump plate easily operated.
Write for "A-C" Catalog.



"Side-Dump"

— **Self-Cleaning Stoker** meets the needs of a wide range of plants for a self-cleaning stoker that may be installed at moderate cost.
The side dump plates drop the ash into shallow ash pits, slightly below the floor line, permitting easy removal. Only slight excavation required. This stoker has a fuel burning capacity of from 1,500 to 1,800 pounds of coal per hour and serves boilers up to 300 H.P. in size. The basic Jones features make this stoker a fuel, labor and money saver.
Ask for description.

Permanent Statistics for the Power Plant

This Is The First Of A Series Of Articles Dealing With Power Plant Costs And Data. The Method of Recording Details Of Plant And Equipment Are Shown Here

By ROBERT JUNE

COMPLETE permanent specifications of equipment, properly filed, are not found in as many modern power plants as they should be. This is due rather to neglect, or lack of knowledge of how to proceed to keep these statistics in good shape rather than to lack of appreciation of their importance. It is indeed unusual to find the power plant in which the operating engineers do not have some statistics written down in their pocket note books. Every one will agree that the pocket note book is not the place for this data. It should be kept in a formal manner and the records should be available at all times regardless of changing plant personnel.

The keeping of accurate specifications of equipment installed greatly facilitates the making of repairs. It is of great value when the new engineer comes on the job and it has a very important function in the adjustment of fire losses, should such occur.

The presentation of specifications of equipment not only serves as an accurate inventory of the contents of the plant but strengthens the case for the owner and is particularly valuable when the owner has gone to considerable expense to maintain old equipment lost in a fire. Moreover, in the event of a fire, such of the old equipment as it is desirable to replace can be ordered without an instant's loss of time.

The completeness of the specifications should increase with the value of the investment in the plant.

Power Plant Building

Figure 1 indicates the desired specification data on the power plant building. This form is, of course, subject to some modifications, depending on the individual structure. However, all of the information contained in this form should be filed in ordinary cases and if the building is large, additional information will suggest itself.

This information is, of course, of great value in connection with the plan of new buildings and additions, and is also of value to the accounting department in setting up depreciation reserves.

As an illustration of the value of these records, let us suppose that we want to construct an additional building. The specification data tells us where we can match the cut stone or terra cotta trim of the original building. If new equipment is to be installed, we can tell by immediate reference to this sheet what the permissible floor load is. If any of the material of construction, such as roofing, becomes defective, we can readily tell who the manufacturers were and ascertain at once whether a guarantee has been made to cover the life of this particular part.

If we get unusually good service out of flooring, painting, or roofing, and wish to use the same specifications in another building, we can get the data from this sheet.

Boiler Data

The boiler room is often the heart of the entire plant. If something goes wrong with the boiler, it affects progress in all departments. We need to have complete information regarding the boilers available at all times.

True, we usually have blueprints, or ought to have them. The actual installation, in some instances, may vary from the blueprints, and there is a certain amount of information regarding the boilers to be obtained from the specifications furnished by the manufacturers.

It is possible to put all this information in one place and on a single sheet, Fig. II.

Economizer Data

If economizers are installed in connection with our boilers, we want the data concerning them to be as readily available as that of the boilers.

If economizers are equipped with scrapers there is frequent need to make replacements and we also want the manufacturers to guarantee this equipment for us so that we can check up the performance of the equipment.

Figure III gives us this essential information.

The Gas and Oil Engine in the Power Plant

This Article Deals With The Difference In The Two And Four Cycle Type Of Engine, Gasoline, Semi-Diesel, And Diesel, And Some Illustrations Of These Types

By T. H. FENNER

IN THE first article on this subject, the general features of the internal combustion engine as compared with the steam engine were discussed. Its efficiency as a heat engine was shown to be much higher than that of the steam engine, and the reason of this explained.

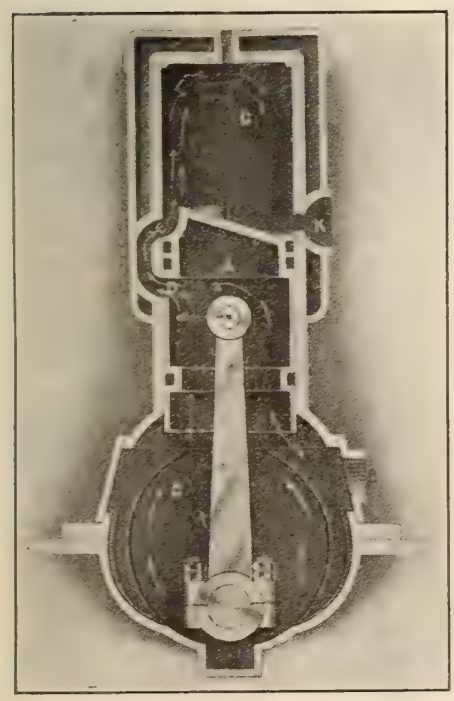
We can now go a step further, and discuss the two important types of internal combustion engine, which are the two cycle and the four cycle respectively.

The Two Cycle

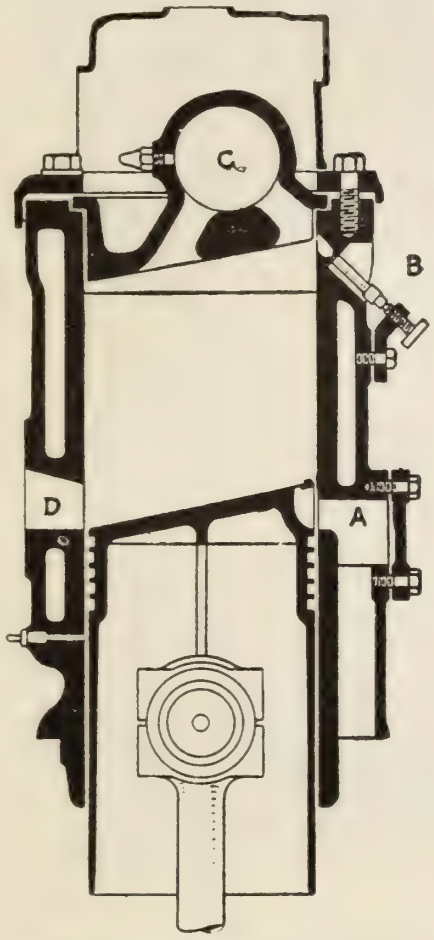
In every gas, gasoline, or oil engine there are four functions to be performed, which constitute what is known as the cycle. These functions are as follows:—drawing in the charge, compressing the charge, explosion of the charge and expulsion of the burned gases or exhaust. These functions may be stated shortly as suction, compression, expansion and exhaust.

In what is called the two cycle system these functions are performed during two strokes of the piston or one revolution. That means that every second stroke is a working stroke or to state it another way, there is an impulse at every revolution of the crank. The correct definition of this type of engine is "an engine working on a two stroke cycle," but common usage has abbreviated this to two cycle.

We can now examine the action of a



Section through small 2-cycle motor, showing path of gas.



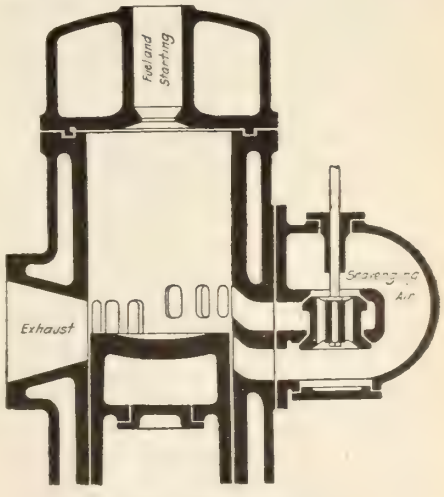
Bolinder Semi-Diesel Engine. A, Scavenging Port. B. Spray Valve. C. Hot Bulb. D, Exhaust Port.

charge in an engine of the two cycle type, and the various methods employed to get a full expulsion of the burnt gases, so as to leave the combustion chamber clear for the introduction of the new charge.

One of the principal features of the two cycle engine is that it requires no valves for the admission or expulsion of the charge and the products of combustion. The necessary openings at the proper times are controlled by the piston itself, which alternately covers and uncovers ports which are cast in the cylinder. In the smaller types, such as small marine engines, and in the semi-Diesel types, the piston on the down stroke compresses the air in the crank case, and at the instant the exhaust port opens or immediately after, the fresh charge is forced through the inlet port, helping to eject the burnt gases in the combustion chamber.

The illustration Figure 1 shows a cross section of a small two cycle gasoline motor. The piston is shown on the bottom of the stroke, and the charge is shown being forced up through the admission port D into the combustion chamber. It will be noticed that the piston is stepped, that is one side is higher than the other. This ensures the exhaust port K being opened for the passage of the exhaust gases before the admission port is opened, and the shape of the piston also tends to throw the incoming charge to the top of the combustion chamber, while the remainder of the burnt gases are being expelled. The fresh charge is drawn in through the inlet port B into the crank case on the up stroke of the piston, while the charge already present is being compressed. At the top of the stroke the charge is ignited, in this case by means of the electric spark plug, and the piston descends on its power stroke. When the piston has gone down a certain distance the exhaust port is opened, and immediately afterwards the piston opens the port on the other side, to admit the mixture of gasoline and air that is being compressed in the crank case. Thus each time the piston reaches the top of its stroke an explosion occurs, giving a power impulse at each revolution.

Figure 2 illustrates a cross section of the "Bolinder" semi-Diesel engine of the two cycle type, which is also furnished with crank case compression for scavenging, but in this case the fuel is injected by a pump through the spray valve B. In this case the piston also



Sulzer Diesel Engine Two-Cycle.

effects the uncovering of both ports for exhaust and scavenging. The port A connects with the crank case, and the descending piston compresses the air in

the crank case and forces it up through the port as the piston descends. The exhaust port D being above the port A is opened by the piston first, and the exhaust gases pass out being assisted when the piston uncovers the port A by the air under pressure rushing up from the crank case. The circular portion of the cover C is the hot-bulb, which is uncooled, thereby retaining sufficient heat to ignite the fuel when it is injected through the spray valve.

The cylinder walls and the cover with the exception of the hot-bulb, are water cooled. This hot-bulb constitutes the chief difference between the full Diesel type and the semi-Diesel. It is necessary because the compression pressure and temperature in the semi-Diesel are only half of that in the full Diesel, therefore the temperature is not sufficient to cause ignition of the charge.

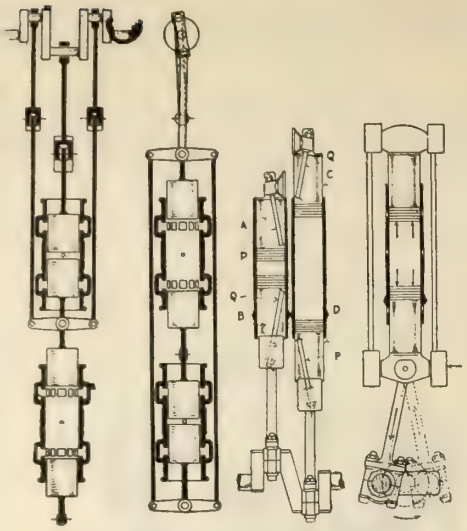
In some types of Diesel engines working on the two cycle principle, the scavenging is performed by means of special pumps worked off the engine itself, which raise the pressure of the air to about 10 or 15 lbs. above the atmosphere thus ensuring a positive scavenging action. This is a most important thing in a two cycle engine, as if the products of combustion are not fully expelled from the cylinder before the fresh charge is ignited, incomplete combustion, with a waste of fuel and power are caused.

Figure 3 is a cross section of the cylinder of the Sulzer Diesel engine, also a two cycle type. The fuel injection is from the top of the cylinder, and in addition to the exhaust port, there are two tiers of scavenging ports. The opening of the lower tier of scavenging ports and the exhaust are controlled by the piston, but the admission of air to the scavenging ports in the upper row is controlled by the valve shown on the side, which is operated by a timed cam. This valve is timed to open at about the time that the lower ports are uncovered by the piston, and can be arranged to close at any time between the covering of the top row of the ports by the piston and the end of the up stroke, or before the piston uncovers them on the down stroke.

The loss of power from the use of special pumps for scavenging air is about the same as the extra power consumed by crank case compression, and constitutes a small portion of the power developed.

The chief advantages claimed for the use of the two cycle system are that a much greater amount of power can be developed in a cylinder of the same size than in the four cycle type, and the absence of any valves makes it simpler of construction, lighter and cheaper.

Aginst this there is the question of efficient scavenging, which is admittedly difficult to obtain, and the absence of which lowers the efficiency of combustion. The cylinder wall surface is greater in comparison to volume in the



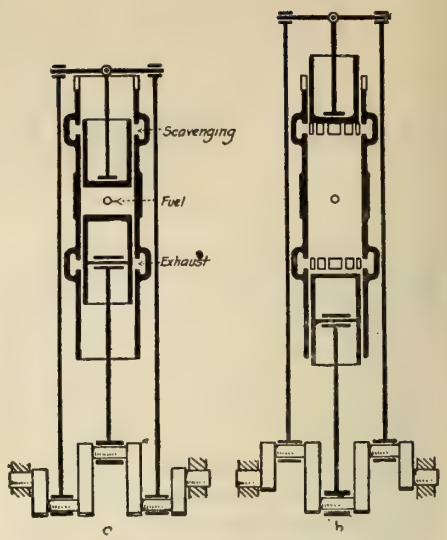
Left.—Junkers Tandem Type.
Right—Cammell Laird Fullagar Engine.

two cycle than in the four cycle, and allows a greater amount of heat to be carried off by the circulating water, which again allows of a higher compression pressure being attained, which of course tends to increase efficiency.

There are schools which favor both types, and both types are being built in large sizes, so the question does not allow of any definite pronouncement in favor of one or the other. Several engines of the two cycle type have been developed on the opposed piston principle which is known as the Junker principle. This consists of two pistons in the same cylinder, the combustion chamber being between the two pistons. When the charge is ignited one piston goes down while the other goes up, the top piston working a crosshead which is connected to two cranks by side rods, the lower piston being connected to the centre crank. In this design there are no cylinder covers, the top and bottom of the cylinder being open to the atmosphere. Another type of this principle is the Fullagar engine, developed by the Cammell Laird Co. in England. In this engine the pistons are connected by diagonal rods, the top piston in one cylinder being connected to the bottom piston in the other. Only two cranks are necessary with this engine, and the top piston carries a square guide which is used for compressing the scavenging air.

The Four Cycle Type

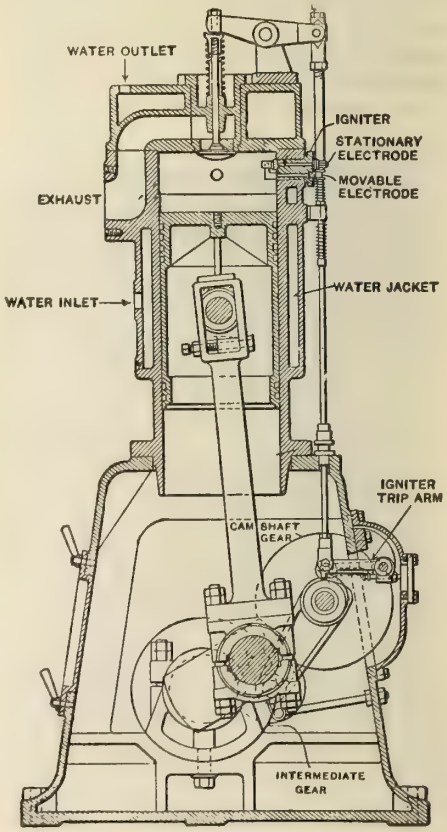
The four cycle type of internal combustion engine differs from the two cycle type in that it receives an impulse only on every fourth stroke, or every two revolutions. It also differs in that it has to be fitted with inlet and exhaust valves for the admission and expulsion of the charge and the products of combustion. On account of the exhaust and charging strokes being entirely separate, the scavenging is complete, and is performed entirely by the piston. There is no connection between the crank case and the chamber as in the two cycle type. It is heavier



Junkers Diesel Engines.

and more complicated than a two cycle engine of the same power. Opening and closing of the inlet and exhaust valves are positively controlled by cams on a shaft which is operated by gearing from the crankshaft of the engine. It is generally considered more reliable than the two cycle type for small high speed motors, but in the larger sizes, and especially in the full Diesel type, the two cycle is about on a par with the four.

In the four cycle type the events occur as follows. On the down stroke of the piston a charge is drawn in through the suction valve. On the upstroke the suction valve closes and the charge is compressed. Firing occurs at the top of the stroke, by means of



Section Through 4-cycle Gasoline Engine.

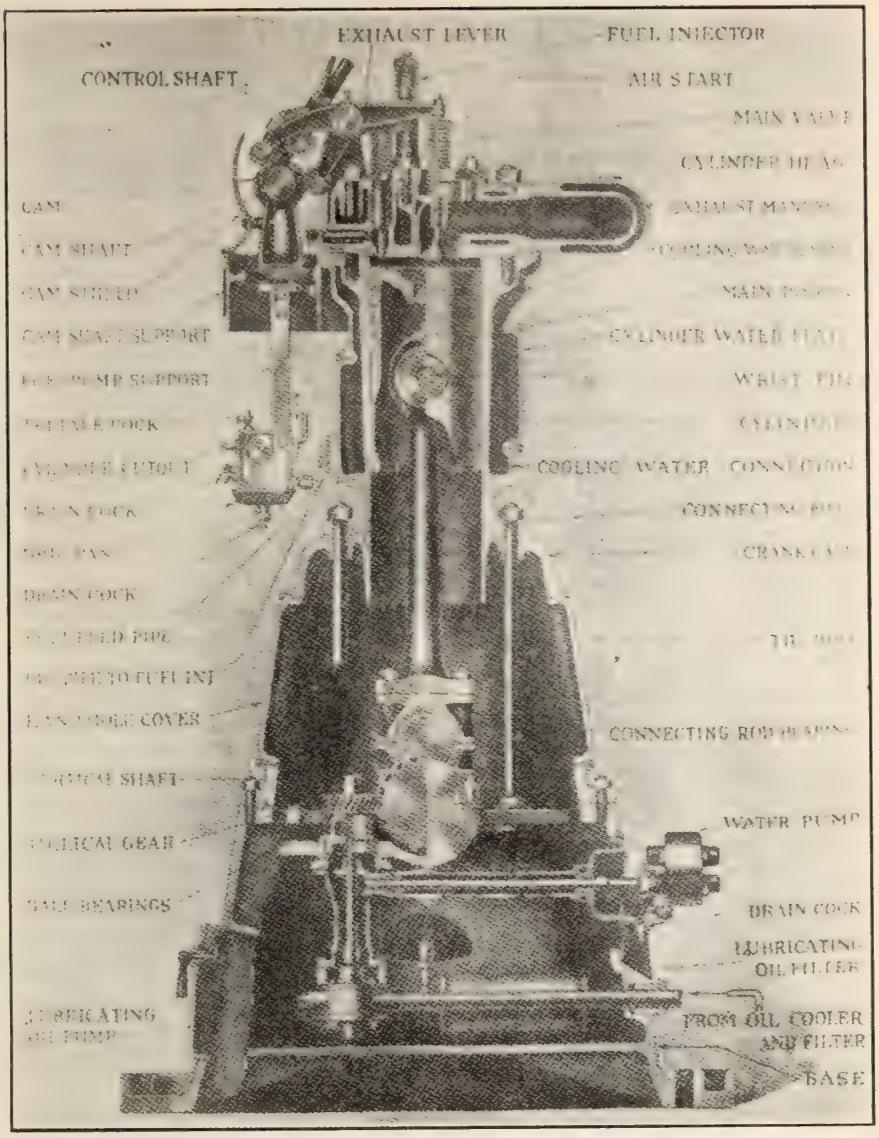
electrical ignition or hot-bulb, or compression according to the type of engine. The third stroke is the working stroke, and on the fourth stroke the exhaust valve opens, and the exhaust gases are expelled by the piston coming up in the cylinder. Thus there is only one power stroke at each two revolutions.

The illustration herewith is a cross section through the cylinder of a full Diesel engine of the four cycle type, as made by the Dominion Steel Products, Brantford. The various parts are shown clearly in the cut. In this type of engine the ignition is performed by the temperature of compression, the air in the combustion chamber being compressed to a pressure of about 500 lbs. per square inch by the ascending piston. The fuel is injected against this pressure by means of a fuel pump, which injects the fuel at a pressure of about 800 lbs. per square inch, and it is atomized by a jet of air furnished by the air compressor which supplies air at about 900 lbs. per square inch. The air compressor is driven off the crank shaft of the engine itself, and is a three stage type. Air is used also for starting, and when the engine is running a reserve supply of air is accumulated in steel bottles or cylinders, this air being available for starting up when required.

In some types of Diesel engines the fuel is injected in a solid jet, the compressed air being used only for starting purposes. This latter type is known as the solid injection type of engine, while the other is known as the air injection. Both these systems have their champions, the Holly injection school claiming the elimination of the air compressor after the engine is once started, and the air injection men claiming better combustion due to the more efficient atomisation of the fuel charge. These advantages about balance each other, and like the controversy between two and four cycle, honors are about even.

There is this great difference between the Diesel type of engine and the ordinary gas or gasoline engine, apart from the method of ignition. In the Diesel engine the charge is ignited and burns for a certain portion of the stroke while the pressure remains constant. In the gas or gasoline engine, the charge is virtually exploded, a considerable rise of pressure occurring at the instant of ignition. Thus in one case combustion takes place at constant pressure, while in the other it takes place at constant volume. The cards from these different types show this plainly, and in later articles we shall give some examples of this.

A cross section of a vertical four cycle gasoline engine is shown in the following cut. The exhaust valve can be seen and the inlet valve is behind this so is not shown. There are only the two valves, inlet and exhaust, there being no need of a fuel injector or air



Section through 4-cycle Diesel engine, Dominion Steel Products.

starting valve, etc., with this type. On large sizes of engines it is usual to install means of starting by compressed air, but on small types starting can be effected by means of a lever on the fly wheel. This is possible owing to the small compression pressure, as compared to the high pressures of the Diesel or semi-Diesel engine. The electrical ignition device can be seen in the side of the cylinder, while the timing shaft is shown working from the crank shaft. The drive is accomplished in this case by means of a chain, instead of bevel or spiral gearing. These two illustrations give a good idea of the general construction of these two types of four cycle engine, but of course it must be understood that practically every maker has some modifications of design that have been developed by themselves.

This article and the preceding one having dealt with the general characteristics of the internal combustion engine, we shall show in our following article some typical examples of different makes, with a brief description of each.

The Newfoundland Government is negotiating with the Armstrong-Whitworth Co., of England and the Reid Newfoundland Railway Co., with regard to the previously announced project to create a water power development totalling 235,000 h.p. on the west coast of Newfoundland. This would be utilized for the establishment of a paper mill with a capacity of 400 tons of newsprint daily; a factory for smelting aluminum with a capacity of 15,000 tons yearly, and other industries.

Preparatory to the commencement of building operations on the new five million dollar plant for the Western University, London, Ont., the board of governors have arranged for the enlargement of the new campus by the purchase of 30 acres of adjoining property. The site thus grows to 230 acres.

Mr. C. Lovatt, 1537 St. Denis St., Montreal, Quebec, is in the market for one 25 h.p. steam boiler.

The Mount Royal Arena, Montreal, Quebec, is in the market for equipment for an artificial ice plant.

For Better Boiler Room Operation

This is the Conclusion of the Paper, First Part of Which Appeared in the Issue of December 20—It Deals With the Instruments Used

By C. W. DEFOREST
Read before the Stoker Manufacturers' Association.

THE following is a description of the instrument and records in use at our plant. It is not intended to convey the impression that it is the best system. It is far from perfect, and we are continually trying to simplify and improve it. However, it serves to show how data are obtained and used at the Cincinnati plant.

Feed Water to the Boilers

The quantity of water fed to the boilers is measured by a Venturi Meter. From the meter chart the pounds of water entering each boiler can be calculated. Valve leakage can be found by co-ordinating this chart with the steam flow chart.

Steam Flow from Boiler

Steam flow from boilers is measured by General Electric flow meters by the use of which the equal division of the load on the boilers is made possible. It also enables the fireman to know that he is operating the boiler at its most efficient rating, which has been decided upon by tests. In addition, the pounds of steam generated can be calculated for future calculations on plant efficiency.

Steam Temperature from Boiler

The steam temperature from the boiler is indicated by a Foxboro recording thermometer. The degree of superheat is calculated from the data obtained on this chart. In addition, it serves the purpose of indicating leaks in baffle work and also the condition of the superheat.

Temperature of Water Entering and Leaving Economizer

The work done by the economizer is determined by the temperatures as recorded on the chart of a Foxboro Recording Feed Water Thermometer. Other information obtained is, factors of evaporation for use in future calculations, condition of economizers; it also gives the operators knowledge as to what combination of auxiliaries to run so as to maintain the correct value of temperature of the inlet water to the economizers.

Temperature for Gases Entering and Leaving Economizers

The information obtained from the chart of Foxboro Recording Pyrometer which measures the temperature of gases entering and leaving the economizers is, whether or not the baffling leaks; whether soot blowers are properly operated; condition of the boiler, superheater and economizer; and whether or not the economizer is operating with a high efficiency. The values of temperatures are also used for heat balance calculations.

CO_2 at Boiler Outlet

The percentage of CO_2 at the boiler outlet is recorded on the chart of a Foxboro-Heath CO_2 Recorder. Uniformity in firing, proper admixture of air into the furnace, condition of boiler and furnace settings, are indicated by this chart. In addition, it helps in building up an efficient firing force, as a check on each fireman can be obtained. The inefficient ones can be picked out and properly trained or replaced. The main purpose of the chart is the saving of fuel.

Pressure at Main Boiler Room Steam Header

This is recorded by a Bristol Recording Pressure Gauge on a chart which indicates the uniformity in boiler operation, and enables the firemen to regulate the load on the boilers to meet the fluctuating demands for steam. It is also used for calculation purposes.

Level of Water in Treating Tank

A graphic chart indicates to the operator the amount of water in the Scaife Treating Tank at any period of the day, enabling him therefore to be on hand when the tank is empty or being filled so that no waste of water results. The various operations of water treating are recorded on the chart and can therefore be checked.

The source of make-up water is the clear well. It is, therefore, essential to know at all times the amount of water in this well. A chart records the water on hand at all times.

Flow of Water Used for Make-up

A V Notch Recorder indicates the quantity of make-up water used. It is valuable in that it assists in determining condenser leakage or valve leakage. It indicates the periods during the day or week when the demands for make-up water are heaviest, thus enabling corrective measures to be made,

Steam Flow to Turbines

The water rate on each turbine can be determined at all periods from the chart of a General Electric Flow meter. Calculations of pounds of steam into each turbine are necessary for calculation on plant and unit efficiencies. Information relative to the condition of the blading is obtained by the indication of high or low rates. The data obtained are used in conjunction with the boiler steam flow for determining the per cent. steam used by the auxiliaries.

Temperature of Steam to Turbine

The degree superheat of the steam to the turbine is obtained from the chart of a Bristol Recording Thermometer. The information is necessary for calculating the total heat of the steam. This chart will also indicate the quality of steam supply to the turbine.

Boiler Room Log Sheet

All data pertaining to boilers on line, banked or out of service, are noted on this sheet. Periodic readings of stoker counters and integrators are also entered on the log. It is used in the calculation of banked hours, service hours and coal used. In addition, it keeps the operator in close relation with the specific work in that he is required to take periodic readings. Taken together, the log sheets form a history of operation and are valuable for reference.

Economizer Log Sheet

This sheet is made out by the economizer tender and is an hourly report on the condition of fan and motor bearings and the mechanism operating the soot scrapers.

Pump Chart

Temperatures of water from feed heaters, feed water pressures, and pump operation are the data obtained from this log sheet. Readings are periodic.

Coal Slips

The amount of coal put into each bunker is obtained from these slips. The data is used for calculating boiler and plant efficiences and coal in storage. Used in calculating Daily Cost Report.

Turbine Room Log

All data pertaining to load, vacuum, oil temperatures, and all other facts of operating conditions are periodically recorded on this log sheet. The calculated results are used in the calculation of plant and unit efficiencies. Here, too, the operator is brought into a closer relation with the work due to the taking of readings. For reference purposes, this log is very valuable.

Daily Coal Report

The purpose of this report is to bring to the superintendent, daily, in a condensed form, all facts pertaining to coal handled on the preceding day. This includes coal received, coal used and coal distribution. The coal storage is therefore known from day to day.

Boiler Room Service Record

This record is prepared daily from the Boiler Room Log and indicates the number of banked hours, on line and total service hours for each day, for the month to date, and since the boiler was washed or bored. From these cards we find which boiler is next due for boring or washing.

Boiler Room Operating Record

The following items of boiler per-

performance are calculated daily for each boiler: hours on line and banked; fuel fired; steam generated; evaporative factor; actual and equivalent evaporation per pound of fuel; boiler rating; boiler and economizer efficiency; per cent. of horsepower developed by economizer.

Turbine Operation Record

The following items of turbine performance are calculated daily for each turbine: hours in service; K.W.H. generated; steam used; load factor; water rate; efficiency of unit; heat transfer of condenser and average circulating water in gallons per minute.

Daily Station Report

All items recorded in the boiler operating records are copied daily on the daily station report, together with the following calculations: total fuel fired; coal per K.W.H. generated and K.W.H. S-O; B.t.u. per K.W.H. generated and K.W.H.S-O; station net thermal efficiency; load factor; peak; and coal and ash analysis.

Boiler Repair Report

This report shows why a boiler was taken out of service, when it came off and when it was back on the line, and what work was done. The work is divided, into—tube replacement, boring tubes, and repairs to brickwork, stoker, piping and valves, and miscellaneous. The cost of work is divided into labor and material charges, and unit costs are calculated where possible.

This system of charts, log sheets and records has been developed with the intention of taking all data which affect the operation of the station, working it over into a set of compact records of each unit of equipment, and presenting these facts daily to the superintendent in such a condensed form that he may keep in close touch with the operation of the station without going over the mass of charts and log sheets.

Conclusions

In conclusion, the following conditions which are vital to better boiler room operation should be emphasized.

1. The best performance of stokers and boilers can be obtained only by employing high grade operators and technically trained combustion engineers;

2. The labor cost for boiler room operation and superintendence is only 2 or 3 per cent. of the total cost. Therefore, it is not the determining factor in the cost of producing power;

If we maintain the maximum efficiency of the plant as a whole, each individual link in the chain of equipment must be kept in good condition;

4. In order to obtain maximum efficiency, such records must be kept of each piece of equipment, as will enable us to know when its performance is dropping below standard.

C. A. S. E. TORONTO LODGE

Second Set of Competition Questions and Answers

Question:—Name the types of boilers in common use, divide into classes, and name the advantages or disadvantages of each class or type under different conditions or load.

Answer:—Horizontal return tube, fire-box, vertical tubular, semi horizontal; fire tube, water tube and fire-box combination with either. The fire tube boiler is suitable for steady load conditions: the water tube boiler is more suitable for varying load or overload conditions.

Question:—What is meant by the surface ratio of a boiler?

Answer:—The surface ratio refers to the ratio of heating surface to the accepted basis for determining capacity, viz:—the ratio of heating surface in H. R. T. boilers is 15 sq. ft. per horse power and the ratio of water tube boilers is 10 square ft. per horse power.

Question:—What is meant by the efficiency of a boiler? What efficiency is usually obtained in properly proportioned boilers with clean heating surfaces?

Answer:—The relation between the "input" (heat of the coal) and the "output" (evaporation of steam,) determines the efficiency; after allowing for certain variables such as temperature of atmosphere and feedwater. The average of 75 per cent. is good and 85 per cent. is very good.

Question:—What is the difference between natural draft, induced draft, and forced draft?

Answer:—Natural draft is obtained by means of high chimneys or smoke stacks but there is a limit to the amount of a given kind of coal that may be burned per square foot of grate surface. Induced draft is obtained by means of suction fans and while it does not greatly increase the boiler capacity it does often eliminate the cost and need of high chimneys or smoke stacks. Forced draft is obtained by blower fans or steam jets and often accomplishes both results, i.e. of increasing the amount of coal that may be burned per square foot of grate surface per hour and avoiding the necessity of chimneys. It also incidentally increases the boiler capacity but the efficiency falls as the forcing increases above certain well-known standards.

Question:—Name two or three methods of producing forced draft. What are the advantages and disadvantages of forced draft?

Answer:—Blower fans, (air pressure), saturated steam jet inducing air and resulting in combination of steam and air blast; also superheated steam and preheated air combination of steam jet. Makes boiler operation independent of atmospheric conditions, but results in higher furnace temperatures than either natural or induced draft.

Question:—What is a mechanical stoker? Give definition and description. What are some of the advantages claimed for mechanical stokers?

Answer:—Any mechanical means of conveying the coal into the fire-box ready for burning may be said to be a mechanical stoker, and they consist of steam operated plungers and pushrods situated in a retort, inclining and moving bars or inclined and stationary bars with clinker breaking or ash dump in centre between the two inclined sides. The advantages of these stokers are that cheaper fuel may be used. It is fed in constantly and regularly, insuring better combustion, and the fire doors are eliminated or seldom used thereby eliminating many objectionable features and losses.

Question:—Into what general classes may mechanical stokers be divided? Point out the difference or advantage of each type.

Answer:—Overfeed and underfeed. In the underfeed type the point of distillation of gases is above the green coal and under the incandescent or hot fires; whereas in the overfeed type the point of distillation is changing from the centre to the top; however, best results are being obtained where the incandescent condition is uniformly at the top of the fuel bed.

Question:—Name two methods of producing induced draft?

Answer:—Steam jet in smoke stack or suction or exhaust fan. The advantages of induced draft are: cost of boiler setting is greatly reduced over that of forced draft; considerable saving can be effected by using shorter chimneys. Disadvantages of induced draft are: the boiler setting must be kept tight, (no air leaks) means of producing the induced draft have to be provided just the same as in the case of forced draft and an interruption to the driving power of same seriously handicaps the operation and capacity of the plant.

Question:—What points should be considered in the selection of boilers for a given plant? Give at least two examples stating reasons for the choice fully.

Answer:—The points to be considered are: the floor space available and head room; also the nature of the load or demand, as to whether it is steady or variable and the range of same; further, the type of fuel to be used and the topography of the country, its relation thereto as to draft, etc.; finally, the water supply should be considered as to scale and its removal. Where load is steady and the draft good, fire-tube boilers may be operated to advantage with almost any kind of fuel, if there is ample heating surface provided. Where the load is variable and liable to heavy demands water tube boilers could be utilized to advantage and forced draft substituted for natural draft.

Testing of Locomotive Superheater Units

THE USUAL method of testing superheater units by means of the cold water pressure method is to use a pump to obtain the necessary pressure. However, in the Grand Trunk Railway Shops at Point St. Charles, Montreal, a clever apparatus for testing these units has been constructed whereby the pressure is obtained from the regular high pressure hydraulic lines of the shops. This does away with the necessity of a special pump. Two other outstanding advantages are the facts that the work is accomplished in perfectly dry surroundings, and that the water is completely expelled from the units into a pit at the conclusion of the test, which is accomplished in a remarkably short time.

The sequence of operations, perhaps, would be the best method of describing the apparatus and its method of functioning. First the unit is clamped by one "T" headed bolt to one side of a "T" casting which takes the place of the superheater header in actual service. The 45 degrees bevel seat in the casting fits the spherically ground end of the unit. The outer end of the unit is supported on a special adjustable stand.

It might be well to mention here that the apparatus is of a dual nature. There are two sets of seats for units to be tested. While a unit is being removed and another one attached to one side, testing operations are being carried on, on the other side of the apparatus.

As soon as a unit is clamped in position, a valve "A" (Fig. 3) is opened that lets city water into the unit. At the same time the lever valve "B" (Fig. 1.) is opened which permits the air to be expelled from the unit. (It will be noted that water entering one arm of the unit through valve "A" expels air through the opposite side of the unit.) To this latter valve an overflow pipe is attached leading down into a pit below the floor, but the end of this pipe is at the same time in open sight, as will be seen in Figs. 1 and 2. When the unit is filled with water a solid water discharge from this overflow is seen. Then the valve "B" in the overflow line is closed. Immediately the full city pressure is conveyed to the unit, the level valve "C" (Fig. 1.) is then opened and its corresponding valve on the opposite side of the apparatus is closed. The gauge now registers the pressure in the unit as supplied by the city mains. Following this the city pressure is cut off by closing valve "A".

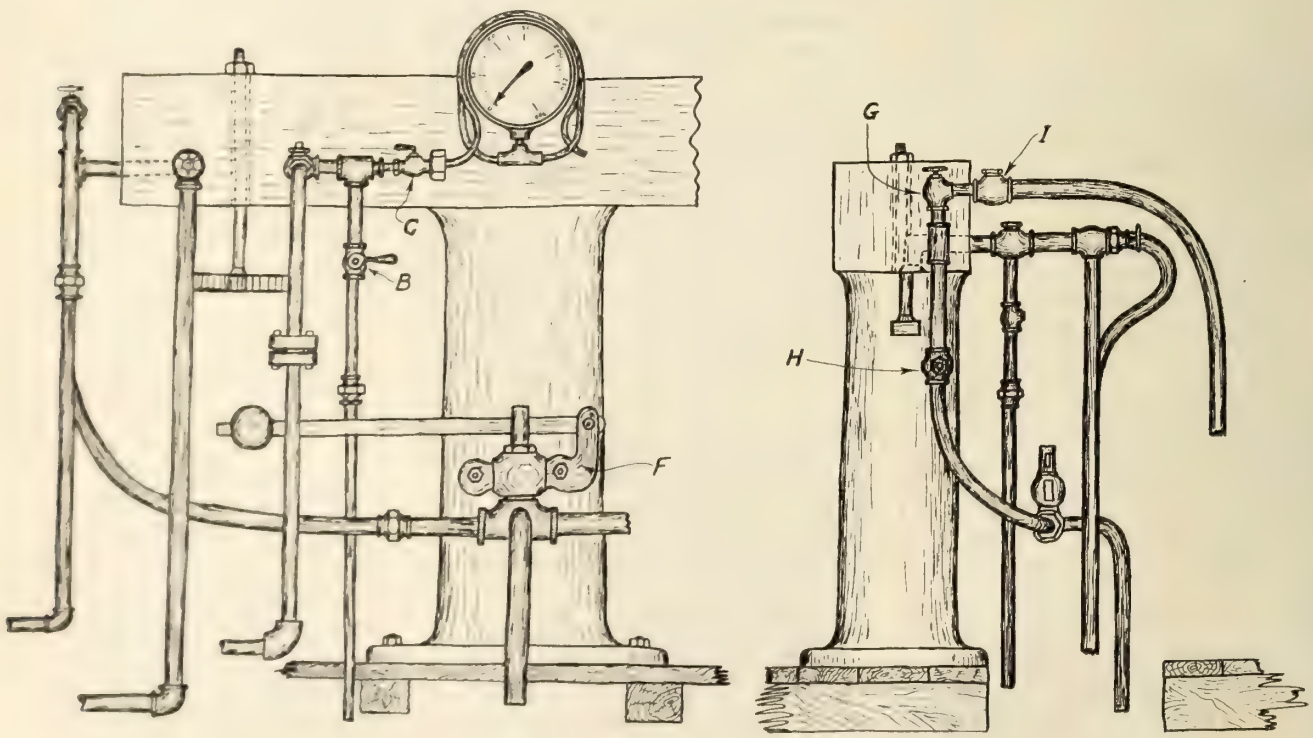
The gauge is connected to a "T" from which two leads run, one to each side of the apparatus. In each of these two lines of 5-16 inch copper tubing, a small lever operated valve is placed to enable the gauge to indicate pressures on either side of the testing apparatus. Between the ¾ inch city pressure supply line valve "A" and the header casting is a high pressure brass check valve, "D" (Fig. 3.) also the nipple between the check valve and the header is made from high pressure piping. This check valve "D" is to prevent injury to the low pressure lines in the event of the operator carelessly leaving the valve "A" open. It also prevents any wasting of water from the high pressure lines.

The gauge as before mentioned, indicates the pressure in the unit at the time the city supply is cut off. Next, the high pressure valve "E" (Fig.3.) is opened with a detachable handle which fits on the square extension of the valve stem, and water from this line at a pressure of 1,500 pounds per square inch is introduced into the unit through an opening 1-8 of an inch in diameter. The gauge slowly climbs until a pressure of from 250 pounds to 275 pounds per square inch is indicated. At a predetermined point the weighted relief valve "F" (Fig. 1) is set to open. Discharge from this valve goes into the pit, as shown in Fig. 1. Then the unit is examined all over for leaks. Next the high pressure water is shut off and the overflow valve "B" (Fig. 1.) opened. Following this compressed air is forced into the unit by opening valve "G" (Fig. 2.) ejecting all the water into the pit below.

The unit is then removed, and another inserted. Should a leak develop a welding outfit is used to weld the pipe on the spot and again the pipe is tested. The relief valve is connected to both sides of the apparatus, and by means of two valves it can be placed in the line of the side in use. One of these valves is shown at "H" (Fig. 2.) They are operated by the same detachable crank as operates the valve "E."

Check valves are also provided in the air line so that no water can accidentally be admitted to the air lines. One of these check valves is shown at "I". (Fig. 2.) Each side of the apparatus is provided with separate and independent air, high and low pressure water, and overflow lines, with independent operating valves. The gauge and relief valves only, are common to both sides. They are thrown over from one side to the other by means of valves as shown.

The high pressure line delivering water to the unit is ½ inch high pressure pipe. That is to say it takes ½ inch



Figs. 1 and 2, showing both the side and end view.

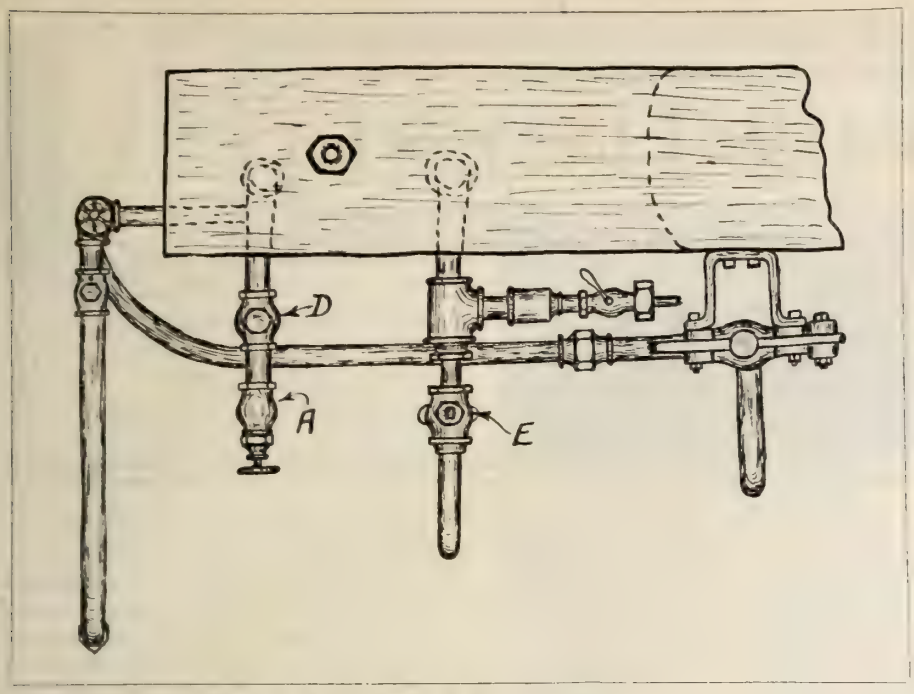


Fig. 3—A Plan View of the Apparatus.

fittings but the actual inside diameter of the pipe is about 5-16 of an inch. The lines leading to the relief valve are also ½ inch high pressure pipe. This permits of ample protection as the high pressure intake opening has been reduced to a diameter of ⅛ of an inch. Regarding this, it may be stated that a much smaller intake opening would be sufficient, but when using a smaller opening, say 1-32 of an inch, or 1-16 of an inch, difficulty is encountered with small bits of foreign matter in the water, clogging the opening.

The air line is ½ inch standard pipe, and the overflow line from valve "F" is ¾ inch pipe. Originally the seats in the "T" shaped header casting were spherical, in order that they fit the spherically ground ends of the units. These seats sometimes leaked and it was found that a 45 degree bevel seat, giving line contact gave practically perfect results.

C. A. S. E., MONTREAL NO. 1

On Dec. 23rd, Montreal No. 1 held an open meeting for the engineers and their friends.

Mr. Moore of the firm of Moore and Goldie, engineers and contractors, was in the chair. Brother Wright A. M. E. I. C., who is giving a series of lectures throughout the winter months on all branches of engineering, took for his subject, Boilers, Mechanical stokers, and Mechanical draft.

A lot of discussion arose as to mechanical versus natural draft plants, and their individual efficiencies and cost.

Brother Wrght then took the prime cost of various kinds of plants installed in Canada and the U. S. A., with the statistics of each, and proved to the satisfaction of his audience, that his assertions were based on prime cost, maintenance, depreciation and efficiency, according to the size of the different plants and their environments.

At the close of the meeting, a hearty vote of thanks was tendered the lecturer, who responded in an able manner, and stated that he was trying to gather the manufacturers together, with the cooperation of various members of the Engineering Institute of Canada, to take an interest in the C. A. S. E. as he thought that in years to come the C. A. S. E. could be of great assistance to them in their various enterprises, which according to "seers" would be of a magnitude more than usual.

QUICK PULLEY COMPUTATIONS

By W. F. Schaphoist

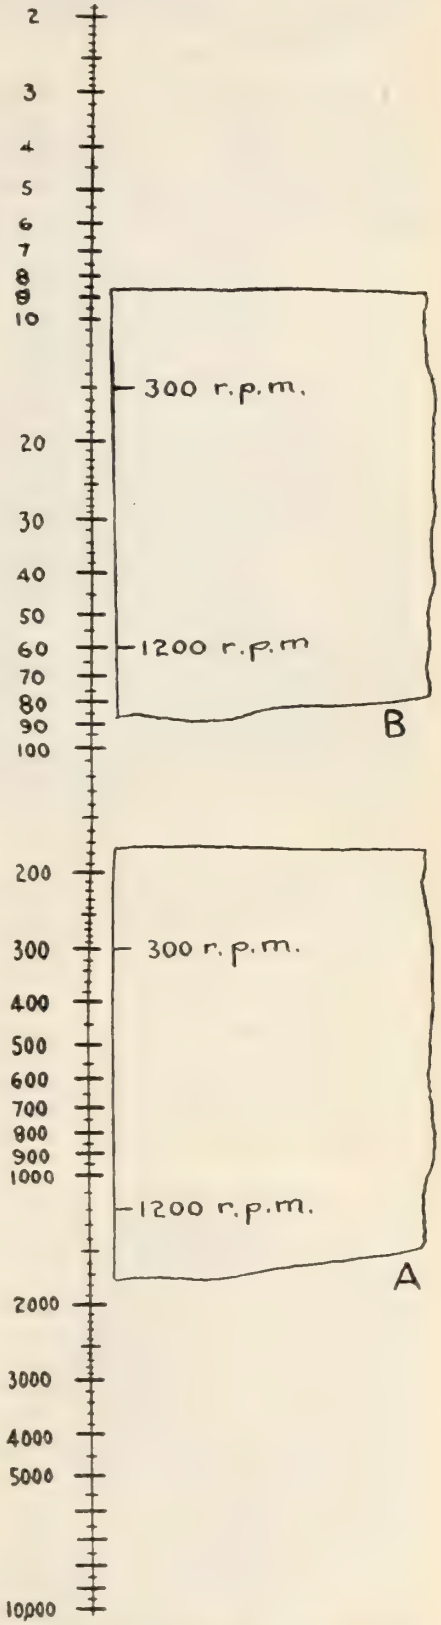
(All Rights Reserved)

The simple chart shown does away with formulas for making pulley computations. It will be found to be exceedingly quick. Just slide the slip of paper from position "A" to position "B" and the problem is immediately solved.

For example:—A motor running 1200 r.p.m. is to drive a line shaft at 300 r.p.m. What sizes of pulleys should be used? On the slip of paper in portion "A" make marks opposite the 300 and the 1200 as I have done. That's all you need do; but if you want to write down "300 r.p.m." and "1,200 r.p.m." also, all right—it doesn't make any difference.

Then slide the slip of paper up to wherever you want it. Position "B" shows that pulleys 15 inches and 60 inches in diameter respectively will do the work very well.

If those diameters are considered too large just shove the slip a little higher and choose the best diameter. No matter where the slip is placed, the ratio is always correct—no figuring is necessary. The chart also lends itself readily to the solution of such a problem as —knowing the pulley diameters, and knowing the speed of one of the pulleys, what is the speed of the other pulley?



This chart could well be clipped out and pasted to a piece of cardboard for general use.

Freak Fuel Savers

FROM time to time there is offered to the public in general, and the engineering public in particular, some novel method of saving fuel which claims to be able to perform a revolution in all established practice.

Too often, these wonderful discoveries emanate from men but with little practical experience and even less theoretical, (technical is a better word,) knowledge. Their ideas are founded on a lack of fundamentals, so that the cold light of scientific fact turned upon them pierces the armor of verbiage in which they are clad, and exposes the skeleton underneath.

The principles of combustion are so well known, or they should be so well known, to all who are interested in the generation of steam by means of oil or coal fuel, that it is difficult to see how these earnest, if misguided, people are able to deceive themselves so thoroughly as to deceive others who have not had the opportunity to become acquainted with these principles. They do so, however, and very often succeed in convincing otherwise hard-headed business men that they have discovered a sort of elixir of life as far as fuel is concerned.

Their claims are as a rule so exaggerated that their nature should draw suspicion on the proposition as soon as it is mooted. A saving of at least 25 per cent. is spoken of glibly, and in some cases the saving is claimed to be 50 per cent. When it is considered that with the very best appliances, developed over years of intensive study by scientists and manufacturers, with the help of practical experience in large units, an efficiency of 70 to 75 per cent. in ordinary practice is considered very good, it is difficult to see how anyone can come along and make a saving of 25 to 50 per cent. at one jump.

There is no doubt that in the ordinary plant, a considerable saving can be made, which may be anywhere from 5 per cent. to 15 per cent., but this could be made without the help of any special apparatus. The exclusion of infiltrating air through the setting, attention to brick work, the correct spacing of fire bars, and a proper attention to draft, will work wonders in the ordinary plant which is running along on the principle of merely throwing so much coal in the fire per hour.

Any competent engineer with a draft gauge and a hand flue gas analyzer could make such an improvement in the average plant that the owner would sit up and rub his eyes when he saw the results.

We would advise power plant owners, and engineers, and anyone else who is running a steam boiler, to look with considerable suspicion on any philanthropist who wants for a consideration to instal something under his boiler that will cut down his fuel bill from 25 to 50 per cent. If he feels that the thing has merit, then he may allow the vendor to put a trial installation under his boiler, the owner protecting himself by demanding proper guarantees from the vendor.

A test carried out under the supervision of a recognised authority in the engineering profession, under proper conditions, which will give the evaporation per lb. coal accurately will demonstrate immediately whether there is any truth in the claims made. Even then, the owner should take the precaution to have his boiler put into ordinary decent shape before he has the first test made, so that he can see what his boiler should do under ordinary conditions without the aid of the special apparatus, so that he is not comparing working under special conditions with working under subnormal conditions.

There is no mystery about combustion of fuel in a boiler furnace, and anyone who can devise a method that will ensure a saving of 5 per cent. from the consumption in a plant that is working at 70 to 75 per cent. efficiency, will not have to search the highways and byways for customers. That is, of course, if the cost of saving does not exceed the saving itself.

Any man who can really and truly build a furnace or devise any apparatus that will make a marked saving in the consumption of fuel for a given evaporation will be performing a valuable service to his country, as well as enriching himself. All the work of the best brains in Europe and on this continent have so far only succeeded in bringing the efficiency of fuel burned under boilers in the very best examples of modern practice to an average of 70 per cent.

If a boiler is working under ordinary conditions at an efficiency of 50 per cent., then half the fuel is being wasted. If someone comes along and claims to be able to save 50 per cent. of the fuel, then he is making the boiler 75 per cent. efficient. If, however, he claims to be able to increase the efficiency 50 per cent., he is making the boiler 100 per cent. efficient, which, as Euclid would say, is absurd.

A NEW TYPE OF FAN

Gardner C. Derry*

In 1916, an engineer of one of the large Power Companies in New York issued specifications calling for an induced draft fan which would at the same time act as a cinder separator. No quotations were received in answer to this request as there was nothing of the kind on the market. Mr. H. F. Hagen, Manager of the Research Department of the B. F. Sturtevant Company, became interested in this problem and started to develop something which would serve the purpose. He was experimenting with a paddle wheel fan, with the runner painted a bright red which was not completely dried. After the fan had been run for about two hours, it was noticed that the driving sides of the tees, rivets, and the inlet portions of the blades were coated with a fine dust. It immediately occurred to Mr. Hagen that there was an action sufficiently strong to separate cinders from the flue gases. This fan had been run in a research laboratory where the air was not polluted with any manufacturing process and any dust which was in suspension in the air would be similar to that found in an office room. If a separation of such extremely fine dust was secured it seemed certain that the action would be successful with the very much heavier cinders.

The idea was then developed to provide buckets at the inlet edges of the blades of the paddle wheel fan. There remained only the problem of disposing of the dust which was caught and separated by the wheel. This proved an easy matter to do as inclined channels were provided leading out into the special dust chambers in the fan in which the dust could settle. Since it was impossible to blow the dust with air, as this would involve again a separation problem, it was decided to permit the dust to settle and fall by gravity into these dust chambers. These dust chambers lead to closed hoppers in which the dust is separated and from which it can be removed periodically or continuously by menas of screw or other conveyors. From the cut shown here, it is easy to see the action of the dust in entering the inclined channels and thence to the dust chambers. Several little guiding vanes will be noticed which serve to direct the air and cinders into the inclined channels.

It was found that this cinder separating fan could be built without taking up any more room and without requiring any more attention than an ordinary induced draft fan. As a fan it proved more efficient than the average induced draft fan in the market and as a separator it was found, on test, to remove 75% of the solid matter in the gases. Naturally the fan removes a much larger percentage than this of the heavy, coarse material but it is this heavy, coarse material which drops over the city in the neighborhood of the power plants causing numerous complaints from the residents in that section.

Two large fans were installed in a large power plant in New York City and proved to be a complete success. These fans are installed in connection with six 500 H.P. boilers and when these boilers were operating at 200% of rating it was found that each fan was removing 250 lbs. of cinders per hour. At higher ratings this would be much greater and it was estimated that if these fans were placed on all of the boilers they would separate seven tons of cinders an hour.

As a passing matter of interest, the material separated at this plant resembled a fine coke breeze and showed on analysis some 9,700 B. T. U. per pound.

The maintenance of these fans is practically negligible. The wheel will last as long as the wheel of an ordinary induced draft fan because the latter is subject to the same abrasive action caused by the cinders against the blades. The housing of the fan will last longer because a part of the cinders never reach the fan housing. The only place where there is any wear is in the cinder chamber of the fan housing. These cinder chambers are provided with easily removable strips of simple forms.

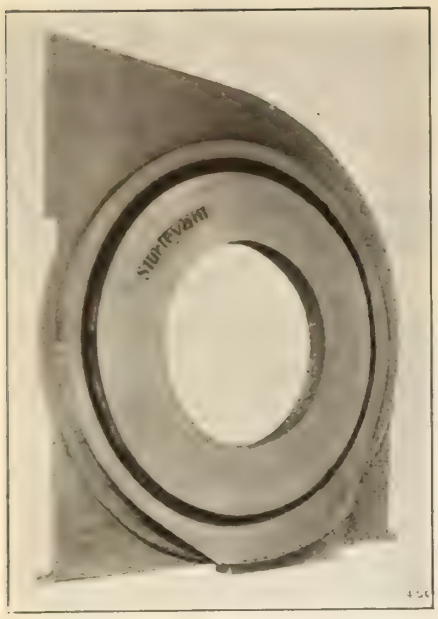
Showing dust channels



View of Casing.

The cinder-eliminating-induced draft fan is particularly desirable for use with underfeed stokers. The underfeed stokers do not cause a serious smoke nuisance, as we usually consider smoke, but when they are operating the boilers at overratings, the necessary high, forced draft pressure blows a lot of the finer portions of the coal over into the stack and these are carried up and discharged over the city. The nuisance thus produced is very serious and is getting more so as boilers are being forced to higher and higher ratings. The extremely fine particles in the smoke are not particularly objectionable because they are carried away by the air currents and are not deposited over the surrounding neighborhood, but the dust and cinders in the gases are fairly heavy and fall within comparatively short distance of the stack.

Many attempts have been made to clean the gases from boilers but the success that has been attained up to the present time has not been sufficient to warrant a general installation of dust removing devices. Usually an electrical system is an expensive proposition to operate and involves a high investment. The washing of the gases, as sometimes resorted to has given fairly good separation but the high up-keep of the washers and flue work makes this method of solving the problem very objectionable. The gases coming in contact with the water form a corrosive unless some non-corrosive material is installed which usually is an expensive undertaking. Another serious difficulty in the above method was that it killed the draft and in some cases it became necessary to by-pass the washer at the higher overloads in order to secure the necessary draft. It is thus seen that the installation when it is needed most requires a fan to supply the draft which is already taken care of in the case of the cinder eliminating fan.

It is readily seen from the above that this fan can be adopted to collect many other kinds of materials. The B. F. Sturtevant Company maintain an experimental fan in their Research Laboratory which is used constantly for trying out new materials which their customers send to them.

In this way they are able to determine the amount of separation that is possible to secure from the fan and also to accurately design the proper size fan for each particular problem which they have to meet.

These fans have been installed in New York City, Rochester, N. Y., Trenton, N. J., Salem, Mass., Fitchburg, Mass., on cinder elimination and they also have the fan operating successfully in connection with boilers using pulverized fuel at the British Columbia Sugar Refining Co. at Vancouver, B. C., besides many of the smaller fans used in the various industries for separating dust from fumes in their various processes.

ELECTRIC HOIST

The Shepard Electric Crane and Hoist Co., of Montour Falls, N. Y. have recently placed on the market an electric hoist. The crane is designed to operate on an overhead runway and can be easily attached to a standard "I" section of the proper size. A fully enclosed motor is furnished with interchangeable frames for direct and alternating current. The motor was especially designed and developed for hoist work, it being carefully insulated and impregnated to protect it from moisture.

The direct current motor is of the standard, series wound, interpole type. The no load speed is twice that of the full load speed, so that a light hook is handled twice as quickly as a full load. The induction motor furnished for alternating current may be either the squirrel-cage or the slip-ring type. The squirrel-cage motor is used with the single speed control and the slip ring type with the variable speed control. As just mentioned, single speed and variable speed controllers can be furnished for either type of motor. The direct current variable speed controller gives from eleven to thirteen speed changes according to the size of the motor. When alternating current is used eight running speeds are available. The controllers, like the motors, are readily accessible although fully enclosed and well protected against dust and moisture. All parts of the mechanism, including the resistance, can be removed without disconnecting a single wire. The contacts and brushes can also be removed without disturbing other parts of the controller. A mechanical brake of the multiple disc type is provided, the function of which is to automatically hold the load when the motor is at rest. It also prevents excessive speed when lowering. An electric brake of the multiple disc type brings the motor promptly to rest when the current is cut off intentionally or otherwise. An automatic limit switch prevents overrunning of the load hook.

ANNOUNCEMENT

Mr. W. O. Renkin has become associated with the Hardinge Company, Incorporated, 120 Broadway, New York, N. Y., in the capacity of Managing Engineer of the Quigley Pulverized Fuel Department, since this department of the Quigley Furnase Specialties Co. has been acquired by the Hardinge Company, Incorporated.

We are informed that Mr. George Farrow, Mount Dennis, Ontario, has been appointed representative and demonstrator in Ontario of the Wm. B. Pierce Co., Buffalo, N. Y., handling the Dean boilertube cleaner.

Mr. O. M. Rau, formerly Consulting Engineer to the Philadelphia Rapid Transit Co., has now become associated with the Hardinge Company, Incorporated, 120 Broadway, New York, N. Y., and will specialize in the handling of Quigley Pulverized Fuel Systems as applied to boilers. This change took place with the acquirement by the Hardinge Company, Incorporated, of the Pulverized Fuel Department of the Quigley Furnace Specialities Co.

NEW BOOKS

We have received a catalogue from Theo, Audel & Co., describing their new set of books for engineers and mechanics. This set has been named by the publishers the "Master Set," and consists of twelve volumes covering the usual subjects appertaining to stationary and marine engineering, and a volume on gas and oil engines.

LARGE CRANK SHAFT

Something approaching a record in large crank shafts was recently achieved in a British engineering works. This shaft was constructed for a large marine engine. It measures nearly forty-three feet long and weighs fifty tons. Much more notable than its size, however, was the accuracy with which it was finished When the shaft was inspected the error in the total length was only eight one-thousandths of an inch, while the maximum error in all the bearings did not exceed twelve ten-thousandths of an inch.

SIMPLE HYDROHOIST

One of the simplest forms of pump consists of an endless chain in the links of which, owing to their peculiar shape, the water is trapped and raised. The mechanism, in fact, operates as a water hoist. In order to make it more efficient a British firm has introduced a very ingenious modification. A wire rope is used, and on this rope are threaded a series of small steel cups, each with a thimble at its centre to keep it at the right distance from its neighbors. When the rope runs at 600 feet per minute this hoist will deliver 3,500 gallons per hour. Curiously enough this delivery represents more than a solid column of water of the diameter of the cups. The cups rise full of water, and there is in addition a large quantity carried on the outside.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

TESTING OF OIL

Question:—Could you tell me through your columns of some method of testing oils and the apparatus necessary for this purpose?

Answer:—Tests for the quality of oil can be made only on proper instruments to be of real use. These tests are for viscosity, flash point, and firepoint. The viscosity tests are made on instruments called viscosimeters, and the principle is the time required for a definite quantity of oil, usually measured in cubic centimetres, to pass through a known orifice while at a certain temperature. The chief of these instruments are the Saybolt, the Engler, and the Redwood. These are commercial instruments, and while they do not give laboratory accuracy, are sufficiently accurate to make comparisons of different oils with each other and with water. Sterling's handbook says: "The proper viscosity for a motor oil is determined by the piston ring clearance and the conditions of the rings and the cylinder walls. A wide clearance or worn rings, either of which cause poor compression, requires a high viscosity oil in order to secure the best results. If the piston rings are closely fitted to the walls a light-bodied oil should be used. If too light an oil is used, too much oil will get past the piston rings on the suction stroke, and, on the compression strokes of the fuel mixture, will leak past the piston rings and condense in the crank case, reducing the viscosity of the oil. If the oil is too viscous there will be a loss of power. Good compression depends very largely on proper lubrication."

It seems that the only proper way to get a cylinder lubricating oil is to experiment till you find the one best suited to your particular case.

The flash point of oil is found by heating a quantity of oil in an open or closed cup, and determining the temperature at which the vapor coming from the oil can be ignited. The closed cup method is said to be the better of the two. The fire point is the temperature at which the vapor can be ignited and remain burning, while the flash point is that at which the vapor ignites and goes out again. Authorities state that the flash point of an internal lubricating oil for a motor has little importance in practice. All motor oils have a flash point that is above that necessary for the purpose they are used for.

OIL IN BOILERS

Question:—I am in charge of a heating plant with two 16 feet by 66 inch dia. boilers and one 12 feet by 48 inch boiler. The two large boilers are used for heating, and are fed from the returns. The boilers carry about 30 lbs. pressure. We use three pumps which exhaust through an oil separator into the heating system. Would an occasional dose of soda overcome the oil before it would drop to the boiler plate? Is there a mineral cylinder oil on the market that would not injure a boiler if it did get into it?

Answer:—The safest way to deal with oil is to prevent it getting into the boiler in the first place, as after it once gets in, it is very difficult to deal with it by means of chemical action. With an efficient oil separator and a reasonable amount of oil in use there should be no oil getting into the boiler at all. If there is an open heater in use, the presence of oil should be detected floating on the water in the gauge glass of the heater, and thus give warning. One means of dealing with oil in the boiler is to blow it off through a surface blow-off, which is an easy thing to install in a H. R. T. boiler. Any oil that gets into a boiler is dangerous. If the oil separator is not efficient, a good filter will do the trick. There are a number of these on the market, or they can be made with the help of a perforated plate and some Turkish toweling or cheese cloth.

HORSE POWER OF GAS ENGINE

Question:—How can I find the horsepower of a three cylinder gas engine, 12 inches dia. x 18 inches stroke, 240 R.P.M.?

Answer:—The horse power of a gas engine can be found from the formula

$$\frac{P \times L \times A \times N}{33000}$$

where P is the pressure per square inch on the piston, L is the length of stroke in feet, A is the area of the piston, and N the number of strokes per minute. The horse power will depend on whether the engine is of the two-cycle or four-cycle. If a two-cycle there will be a working stroke every revolution, while the four-cycle only has a working stroke every two revolutions. The average mean effective pressure is about 70 lbs. per square inch so that if your engine is a two-cycle the formula would be

$$\frac{P \times L \times A \times N}{2x33000}$$

and if a four cycle

$$\frac{P \times L \times A \times N}{4x33000}$$

With a diameter of 16 inches the area of piston would be 16x16x7854 and the stroke 1.5. Then

$$\frac{70x1.5x201.06x480}{2x33000} = \text{I.H.P.}$$

for two-cycle and

$$\frac{70x1.5x201.06x480}{4x33000} = \text{I.H.P.}$$

for a four-cycle on each cylinder. This would give for two-cycle 153.5x3=460.5, on three cylinders, and for four cycle 230.25 on three cylinders.

DIAMETER OF SHAFTING

Question:—Would you please figure out for me in your "Question Box" what size of shaft is required for a stationary engine having an overhung crank. Size of cylinder 14 inches, stroke,14 inches. Revolutions 195 per minute. Boiler Pressure 110 lbs. per sq. inch.

Answer:—For the diameter of an overhung crank shaft, which differs from a shaft having two bearings by the fact that there is a bending moment as well as a twisting moment, an approximate formula is diameter equals .4 x dia. of cylinder. Using this formula the diameter is

14 x .4=5.6 inches.

In order to get an absolutely accurate estimate, a great many more particulars would have to be known. However this formula has been arrived at by plotting curves from the diameters of six different engines in which the combined twisting and bending moment has been fully worked out, and found to follow very closely a straight line law.

RATTLING IN CYLINDER

Question:—We have a 16-inch by 18-inch high speed engine running at 225 r.p.m. with 110 lbs. of steam. This engine when under load runs very quietly,

but when running light there is a very loud rattle in the cylinder. There are two rings on the piston, ⅝-inch by 1½-inch. The rings and cylinder appear to be in good condition. Would you kindly give me some information through Power House on the cause of this rattle in the cylinder?

Answer:—We take it that the engine is a fly-wheel governor type, as most of these engines are. It is not an unusual thing to hear a rattle in the cylinder of these engines when running light, and it is caused chiefly by the very early cut-off and high compression on the return stroke due to the automatic governor. This compression is at times high enough to cause a momentary lifting of the slide valve from its face, and the accompanying return causes a sound like a rattle. There is always a tendency to a little play in the piston rings due to the pressure behind the piston falling below the atmosphere when cut-off is very early and excessive cylinder condensation will also occur, which usually causes a cracking sound. Some of the rattle which seems to be in the cylinder may be in the guides, if there is any slack in them, and will be caused by the flywheel pulling the engine round during part of the stroke, and lifting the slipper against the top guide.

As long as your engine runs quietly when under full load, which we presume is the normal way of running, a little rattle at light loads is not a very serious matter. Any slight slackness is more likely to show up when running light than when under a steady load.

EFFECT OF HIGH ALTITUDE

Question:—Will you please explain why a semi-Diesel engine will develop more power at the sea level than at a higher altitude? Is it because there is more moisture in the air or because a greater volume of air enters the combustion chamber by reason of greater atmospheric pressure? When purchasing my plant two years ago the makers informed me that it would develop 25 horse power at sea level but at an altitude 2,000 feet above that, I would lose about 3.4 horse power. Under actual running conditions last winter I found that with a load of 115 volts and 120 amperes she would choke herself and stop. This happened on several occasions and I was at a loss for a reason because this is only 13.8 K. W. I later installed a water injection (which is strictly against the rules) with the result that I can now develop 125 volts and 16 amperes with ease.

Before installing the water feed she would pound like everything as soon as the load began to come up around 110 amperes, but now she is as silent as any steam engine with a far bigger load. I would like to hear from some of our fellow-operators as to their opinion and experiences in this line.

There are several engineers in this district, one of them a graduate of Manitoba Agricultural College, who laugh at the idea of water injection, but I can show them where it works on my outfit.

Answer:—The cause of internal combustion engine developing less power at a high altitude is because of the rarefied atmosphere prevailing at that point. This leads to a lesser weight of air per cubic foot, and the volume of the cylinder remaining constant, the weight of air pressure stroke and the compression pressure is lowered, thus leading to lower powers. This has been especially noticeable in airplane engines reaching great heights, and to overcome it, supercharging has been resorted to. This is simply a means of compressing the air before its admission to the cylinder, thus counterbalancing the lesser density at the high altitude.

Water injection has been used on gasoline and oil engines with success at various times, and there is no doubt that it has a beneficial effect in cooling the piston head and cylinder walls. In this way it lessens the chances of pre-ignition and the deposit of carbon, and tends to a smoother working engine. It has been objected to as being an unnecessary complication, and as having a tendency to cause corrosion. Used in the small quantities that are required there is not much danger from this cause.

The heavy pounding noticed by you previously was no doubt due to pre-ignition, which would be caused by hot carbon deposits on piston head. These deposits were no doubt caused in the first place by incomplete combustion due to the poor mixture of air. Pre-ignition would lead to more incomplete combustion and more deposit so that the remedy applied by you in the water injection, undoubtedly had a good effect. The evaporation of the water into steam would have a considerable cooling effect, and the steam generated would have a good effect on the compression.

It does not seem to us that there is much to laugh at, especially as you have proven the benefit in your own particular case. What do the builders say?

A BOILER SCALE PARADOX?

By W. F. Schaphurst

Many engineers of much experience have never thought of this easily explained truth—that the boiler tubes that are cleanest scale the most. Sounds like a contradictory statement, doesn't it? Yet it is a fact. The catch that "gets 'em" is that the word "outside" is omitted. In other words, the tubes that are dirty with soot will not be so dirty inside, because soot is about as good an insulator as there is against the flow of heat. Authorities who should know declare that soot is a more effective insulator than asbestos, and that is "going some." To cause all boiler tubes to scale an equal amount in a given time, therefore, it behooves the operator of the soot cleaning machine to keep all tubes equally clean, from top to bottom. And even then, perhaps, there will be considerably more scale to be found in the bottom tubes where heat is most intense. The tube that absorbs the most heat will evaporate the most water, and therefore will leave the most scale to cling to and impair the heat transmitting qualities of the tube. Thus the boiler tube is "twixt the devil and the deep sea" in that it is beset on both sides by a substance that is injurious to the plant owner's pocket book, directly through the coal pile—soot on the outside and scale on the inside. If it is a fire tube boiler the reverse is the case.

This explains why it is that in many boilers scale in the tubes is thicker on one side of the tube bank than on the other. In such boilers it is invariably found that the soot is blown off the tubes through the dusting doors at the sides of the setting. The cleaning, however, is not THOROUGH enough because the boiler is not equipped with the proper kind of apparatus for regular cleaning. A hand lance thrust through the dusting doors does not clean the "far side" of the boiler. Instead of cleaning the tubes on the far side it blows the soot from the "near side" over onto the tubes farther away, and makes matters worse. In some cases it has been found that tubes have been packed completely full of soot, and they might just as well not have been in the boiler at all. By looking into the problem with care, and studying the cross section of a typical horizontal water tube boiler, it will be readily understood why and how it is possible for the tubes to become packed full of soot where hand lance blowers are constantly used.

The better way to clean off the soot is to install a permanent cleaner on top of the tube bank and blow down between the tubes. The soot is thus cleaned off from one side to the other in a uniform manner and instead of having the jets blow against the wall the jets blow the soot downward into the clean space below the tubes. It is impossible, in designs of this kind, for the tubes to become clogged full of soot. Scale formatin, also, will be uniform from side to side. It has been pointed out that during the scaling process some of the workmen may "think" that the scale is thicker on one side than on the other. The thickness, it is said, varies directly with the tiredness of the man. There may be some truth in that statement but it nevertheless does not alter the above.

It has also been said that much depends upon the way in which the fireman shove's coal into the furnace. If he is left-handed, he may throw more coal onto one side than the other and thus keep one side of the boiler hotter. There may be some truth in that, but the fact remains that the tubes that evaporate the most water or absorb the most heat are the ones that will have the thickest scale.

Practical Electricity for the Engineer

By G. R. ARCHDEACON, A.M.I.E.E.

Doubtless many of the readers of Power House are already asking themselves the well-worn question, "What is electricity?"

To be perfectly candid I do not know; but what is still more surprising is that I am unable to find any person who can give me this much-desired information. No one has ever heard, seen or tasted electricity. We see many effects of electricity, many results which follow the presence of electricity, but the thing itself remains to be actually discovered. Fortunately for mankind, it does not really matter whether we know what electricity is or not, for we have learned how to control it, and apply it to our daily needs.

Electricity And Magnetism

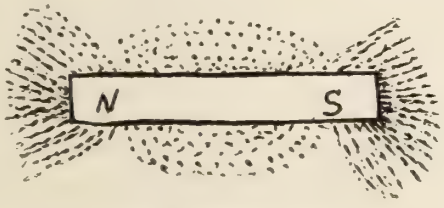
Before taking a wild leap into the intricate subject of the design of dynamos, alternators, motors, etc., it is desirable that we devote at least a portion of our time to the consideration of the various laws that appear to govern the production and distribution of electricity.

The old conundrum of "which came first, the chicken or the egg," may be applied to the study of electricity and magnetism and put this way, "which came first, electricity or magnetism." They are both as hard to answer. Magnetism develops electricity, and electricity develops magnetism, but which of the two came first does not seem to be known. It is therefore necessary that we consider briefly the underlying principles controlling the development of these two forces.

Magnets

Magnets are made of either iron or steel. In the case of the magnet made from iron, the property of magnetism is not permanent, as it is liable to lose its magnetism quickly, or in other words to become de-magnetized. On the other hand the steel magnet retains its magnetism almost indefinitely. Steel magnets are therefore generally termed "permanent magnets."

To produce a permanent magnet it is only necessary to take a piece of steel and rub it on one of the ends of a magnet several times, seeing that it is drawn across the magnet in one direction only. The steel mysteriously acquires this force of magnetism and may retain it for several years, and can be renewed at any time by repeating the above process.



Lines of Magnetic Force.

The magnet made from soft iron is usually an electro-magnet. It is made by winding a few turns of wire around the soft iron, and connecting it to a source of electricity with the result that it becomes magnetised. This magnetism is practically all lost when the electric current is disconnected.

The extremities of all magnets are known as the poles and are called the north pole and south pole respectively. The greatest force is always exerted by these poles, and the force diminishes towards the centre of the magnet. From each of these poles a force of magnetism is radiating in what is known as "lines of magnetic force" or the "magnetic field."

Any body near enough to be affected by the lines of magnetic force is said to be within the magnetic field. Instances of this are seen in the armature of a dynamo, alternator, motor or the trembler of an electric bell.

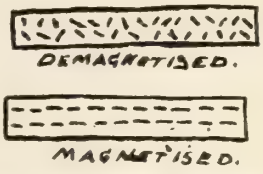
The value of this magnetic field is variable, in the case of a permanent magnet by increasing the area of the magnet pole, but in the case of the electro magnet by increasing the number of turns of wire around the magnet and increasing the quantity of electricity flowing in the wires. To demonstrate the effect of the "magetic field" take a sheet of paper, sprinkle evenly with iron filings, and note the position in which the filings fall. Now insert underneath the sheet of paper a magnet and you will immediately observe the iron filings take up a definite position around each of the poles of the magnet. Fig. 1.

Attraction and Repulsion

We are now in a position to appreciate the fact that a magnetic pole has the power of attracting certain bodies. We have yet to observe another phenomenon, and that it is its power to repel certain bodies.

Take an ordinary pocket compass, place it on a table, and place a bar magnet close to it, gradually pushing the magnet nearer the compass. Immediately the needle of the compass comes within the range of the magnetic field, one end of the compass will point directly toward the magnet, thus proving the power of attraction.

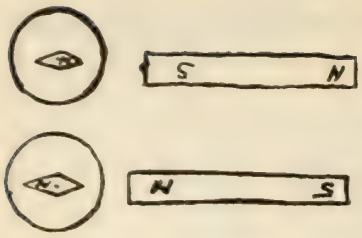
Now present the opposite end of the magnet to the compass, and the needle will be swung the other way, thus proving the power of repulsion. It is this



Effect of Magnetism on Molecules.

power of attraction and repulsion of magnets that makes possible the electric motor, as by mechanically presenting the north and south poles alternately we can cause rotation of a piece of iron placed in the magnetic field.

Magnetism is undoubtedly one of the most mysterious forces of nature. It is found in the form of magnetic iron



Effect of Polarity on Needle

ore in various parts of the world, and was known to the ancients as the lodestone.

One is struck with the remarkable nature of this force when reflecting that if a piece of steel is magnetised, it acquires a force it did not formerly possess, a force which is capable of actually lifting certain bodies. Yet if we carefully examine the steel before and after magnetising, we find in spite of the additional force, there is no increase in weight, or general dimensions, or chemical composition. The only change is in the molecular construction. Whereas before magnetising the molecules of steel were in a state of disorder, after magnetising they assume a regular form as of a company of soldiers on parade.

Magnetism, unlike electricity, is very difficult to insulate. This may be demonstrated by placing a needle on a table and moving a magnet along the underside of the table. Immediately the magnet approaches the needle it will be observed that the needle moves in an attempt to get closer to the magnet, exactly as if there were no table top intervening. This experiment may be repeated with various other materials, definitely proving the magnetic lines of force penetrate all such materials. This characteristic is the frequent source of inaccuracies in supply meters, and various delicate testing and measuring instruments used in the practical application of electricity.

We have already demonstrated that electricity develops magnetism, we have now to prove that magnetism develops electricity.

We are all familiar with the horseshoe magnet. This is only the ordinary bar magnet bent into the shape of a U. If we take a piece of wire and connect both ends to the terminal of a galvanometer, and move the wire up and down between the poles of the magnet, electricity will be developed in the wire, flow through the galvanometer, and cause the movable pointer on the galvanometer to oscillate.

This is precisely what occurs when we cause the armature of a dynamo to be rotated between the poles of the dynamo. Magnetic lines of force are radiating from the poles of the dynamo. The wire on the armature moves up and down cutting these lines of force and we have the electricity which flows on through the cables, to run the street car or to heat up the humble cup of coffee in the electric percolator.

From this demonstration we derive the law of magnets, "Unlike poles attract and like poles repel each other."

POINTERS ON ELECTRO-POWER RATES

By George MacLean

Three subjects that are frequently little understood among men who are responsible for the purchase of power for industrial plants are the flat rates, kilowatt-hours and maximum demand. A flat rate is based on the connected load. Assume an installation of several motors, amounting in all to 200 h.p. and a rate of $40 per horsepower year is charged. Then the cost of power per month is

$$\frac{40 \times 200}{12} = \$666.66$$ for the connected

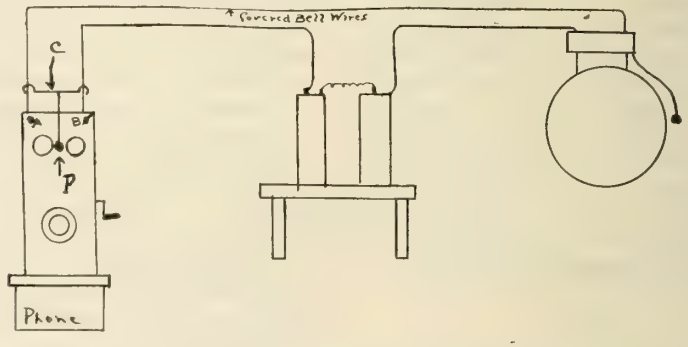
load of 200 h.p. The advantage or disadvantage of a rate of this kind depends on the load factor, or the ratio of the horsepower employed to the motor horsepower. From this it can be readily seen that if only 100 h.p. of the total connected load of 200 h.p. is being utilized, then the connected load factor is 50 per cent. or 50 per cent. of the connected load is being needlessly paid for and produces no return. Thus if the contract is on a flat-rate basis, watch the motors and keep them loaded up to full load, if possible. Also, the processes should be arranged so as to keep all motors in service as much as possible, for when they are stopped the power expense is still going on.

The kilowatt-hour is the equivalent of 1,000 watts for one hour, of $1,000 watt-hours. This method of buying power has the advantage over the flat-rate system, in that only the power used is paid for. If on 200-h.p. connected load only 100 kilowatt, or 134 h.p., is used continuously for one hour, the power consumed is 100 KW-HR. and this is what is paid for. The total 200 h.p. is not paid for, as on the flat rate, but only for the actual power consumed by the motors.

Maximum demand presents a different problem than either the flat-rate or kilowatt-hour rate. A special meter is connected in the circuit, which automatically registers the highest amount of power used over a certain interval of time. If you have contracted for 200 h.p. and the maximum demand does not exceed this, then only 200 h.p. is paid for. However, if the max. is 250 h.p., say for 15 minutes, for any one day during the month, then 250 h.p. is charged for. The reason for this is that the power company is supposed to have to hold in reserve sufficient capacity to meet the needs of the customer. Evidently much can be done to keep the peak loads down by the proper manipulation and arrangement of machinery. For example, if there are a number of heavy processes that operate only intermittently, then, if it is possible to have different processes going on at different times, the load will be much lower than if all were in operation at once.

The maximum demand rate can also be used in conjunction with a kilowatt-hour rate; that is, so much per kilowatt-hour is charged and in addition to this, so much per kilowatt maximum demand for a given interval during the month is also charged.

The output of coal from Canadian mines during the first nine months of 1921 was ten and three quarter million tons as compared with slightly over twelve million tons the corresponding period of 1920, according to a statement issued by the Dominion bureau of statistics. While the production was less than the previous year, it was greater than 1919, when the output of nine months period was 14 per cent less.



LOUD TELEPHONE BELLS

This loud ringing telephone call bell is so easy to install that anyone having use for such a bell should connect one. To make it, install a regular bell outfit, as batteries D and bell E, connect the end of the wires at A and B. Bend a piece of bare copper wire and fit it on the wires as at C. To set it place the end of the bare wire leg on the bell hammer at F. When the telephone rings the leg will fall off the hammer and allow the bare wire to fall onto the phone terminals at A B. This will cause the Bell E to ring until the leg is again raised and placed upon the telephone bell hammer.

The Operators' Point of View

EXCESS AIR AND EXIT GAS TEMPERATURE

Editor, Power House,

The question of heat losses is always an interesting one or at any rate it ought to be and anything that will increase our knowledge of how these losses occur will obviously be of value in enabling us to prevent them.

In "Power" of a recent date, H. D. Fisher in writing on "The Advantage of Nitrogen in the Boiler Furnace," incidentally gives us some information on the effect of excess air on exit gas temperature. He says:—

"It is a mistake to assume that an increased volume of gases will transmit heat to a boiler more efficiently, whether the entering temperature or entering total heat content of the gas is the same. In the first case, the temperature at the entrance being the same the rate of heat transfer. B. t. u. per square foot of heating surface per degree temperature difference per hour, does not increase as rapidly as the velocity, and the higher velocity gas will not be able to give up as much heat per square foot of heating surface passed over, and will therefore leave at a higher temperature, with correspondingly less efficiency.

"In the second case, the total heat content of the gases being the same, the larger volume of gas would be at a correspondingly lower temperature and give a lower rate of heat transfer resulting in a greater proportion of heat carried away by the higher velocity gases."

It will be noticed that Mr. Fisher does not give the "common explanation" given by Mr. Pratt and quoted in Power House of Nov. 21. He goes on to say, "This is shown experimentally, as I have analyzed flue gases from a 5000 sq. ft. hand-fired boiler equipped with flue gas temperature recorder and found that as the fire was changed from a very white hot fire giving 14 to 15 per cent. CO_2 with 0.3 to 1.0 per cent. CO with a flue gas temperature of 490 to 520 degrees, to a redder, cooler fire giving 10 to 11 per cent. CO_2 with no unburned gas, the flue temperature rose to 700 degrees F., the boiler being operated at 125 to 150 per cent. rating. Also in connection with some coal tests on a 5080 sq. ft. water tube boiler with mechanical stoker the following averages were obtained for 10 hours:

	Percentage rating	Developed
	116	109
Flue Gas temp. deg. F	541	586
CO_2 per cent.	10.4	8.9
Oxygen per cent.	9.0	11.3
CO per cent.	0.6	0.1
Nitrogen per cent.	80.0	79.7
Excess air per cent.	76	119

We see from this that a very white hot fire has a tendency to produce high CO_2 and a low temperature fire the reverse.

With 14 per cent. CO_2 the excess air

$$=\frac{20.7-14\times100}{14}=48\% \text{ nearly}$$

With 10 per cent. CO_2 the excess air

$$=\frac{20.7-10\times100}{10}=107\%$$

In addition to the above at the recent meeting of the A. S. M. E., Victor J. Azbe, reported the following tests A, B, and C, in which the effect of excess air is clearly seen.

	A.	B.	C.
Draft drop through fire, in...	3.45	3.76	4.05
Heating value of dry coal, B. t. u.	12,080	12,850	11,864
Per cent. rated capacity developed	102	140	185
Feed water temperature, deg. F.	180.6	187.0	176.8
Steam pressure, gauge, lb...	130	127	129
Temperature of flue gas, deg. F.	612	533	532
Per cent. CO2	7.6	13.3	14.0
Over all efficiency	56.0	68.5	78.1

The excess air in the above tests would be respectively
172% 48.1 48 nearly.

It will be noticed also that although the per cent. rated capacity developed was increased greatly from 102 to 185 the reduction in the excess air lowered the exit gas temperatures from 612° F to 532°.

With these concrete examples given it will be easier to believe the theory expressed in Power House of Nov. 21.

R. MacLaren,
160 Dovercourt Road
Toronto.

TREATMENT OF FEED WATER

Editor, Power House:

In your September 5th, 1921, issue of "Power House," we note article entitled "The Treatment of Boiler Feed Water" by Robert June. In paragraph headed "Boiler Metal Treatment" and referring particularly to Perolin, statement is made that it works its way along the steel, eventually forming an "insulating coating" between the scale and the tube.

We believe that this statement should be corrected, in that it gives an impression that the Perolin forms a coating on the tube, which interferes with transfer of heat, as this is the usual interpretation of the word insulating. We are inclined to believe that the author intended to bring out the fact that the coating prevented the adherence of scale to the tube, but as given in the article, it certainly leads to an erroneous and harmful conclusion.

Very truly years,
The Perolin Company of America,
By E. L. Gross, Vice-President.

C. A. S. E.

The Editor, Power House

I notice in your issue of Dec. 20th, a report of meeting Toronto No. 1. I am very pleased to read of the enthusiastic manner in which they are taking up the Grand Lodge Educational Matter, but one item is in error, viz; that no text books are allowed. I was instrumental in drawing up the rules of this competition and I don't remember any such clause. One rule stated that no magazine editor or magazine could take part in the competition.

Now, as the first set of questions are printed on this page, I would like to ask you, are these Toronto No. 1 own answers, or are they the answers of the magazine? If they are the magazine's own property, I would suggest that the answers be given a wider scope. Of couse, this will be left to the discretion of the examiner in his remarks to the Grand Secretary, and awarding of points.

In my letters to the various lodges I have suggested that formulae could be interspersed with the answers, to impress more fully, the points in question on the minds of those taking part in the contest. On first reading I was rather annoyed at the answers being printed, as some lodges may not have answered it in the form printed, these may become disheartened and take no further interest in the competition. However, after mature consideration, I think this could be put to a better purpose by saying that your answers could be more fully demonstrated, so that at the end of the competition, a good manuscript would be available in the lodge library.

I hope you will see your way to print this, in order that the error may be cleared up.

Yours truly,
Henry Wright,
Vice-President,
& Executive Committee.

Editor's Note.

The questions and answers referred to are published exactly as received from the secretary of the Lodge, and this journal has nothing more to do with them than extending the courtesy of publishing both questions and answers by request of the C. A. S. E. Toronto No. 1 Lodge. The introduction to the article distinctly states that the questions and answers were those submitted at the meeting of the Lodge.

Editor, Power House:—

Educational Contest C. A. S. E.

The following is an Exact Copy of the Rules, governing same, which was sent out to all Subordinate Lodges of the C. A. S. E. by the Grand Lodge Secretary, L. J. Ellis of date Nov. 11, 1921.

Rule No. 1—"Each Lodge to demonstrate in open meeting."

Rule No. 2—"No Lodge to ask information regarding the questions, from any Mechanical or Engineering Journal."

Rule No. 3—"The Secretary will take a copy of the answers (given) and record them in the minute book, he will also send a copy to the Grand Lodge Secretary written on plain paper without any marks or other means of identification. The Grand Secretary will allot each Lodge a number, which he will stamp on the first (copy of answers made) before sending it to the Examiner."

Rule No. 4—"Each set of questions to be sent to the Grand Secretary on the date stamped on the list."

Rule No. 5—"Any Lodge breaking these rules to be disqualified. Bro Ellis to be the final arbiter."

(Signed)
H. Wright
J. J. Sullivan

DOMINION CERTIFICATE

Editor, Power House:—

Having received the last edition of Power House I see by its columns that the discussion on the Dominion Wide Certificate for Stationary engineers is waxing rather warm and I also notice that I come in for my share as well. I wish to say that I had not any intention of finding any fault with my fellow engineers, but rather with the system under which the certificates in Ontario had been granted previous to the coming of the graded certificate. This has started engineering in Ontario on the road to the goal of better engineers and to placing engineers of this province on a par with their fellow engineers of other provinces, where certificates are won by the intelligence of the man writing the examination, instead of having the certificate donated to him. I am sorry that my friend Mr. Wright has taken it that I was finding fault with the engineers. Far from it. If a man asks for a certificate and it is granted him he is not at fault, it is the person or persons who issued the certificate. I only hope that every engineer in this broad Dominion will look into the matter of the Dominion Wide Certificate and lend his efforts to bring it about.

Hoping I have made myself clear re. my position to my fellow engineers, I have the honor to be,

Yours truly,
Frank Moore,
Sarnia.

The Editor.
"Power House:"

The letters in Power House under the heading "Dominion Wide Certificates," are very interesting to me and also to other engineers of my acquaintance, but the Ontario certificate seems to be only a license to take charge of a steam plant for one year. Why should an engineer have to pay one or two dollars every year to protect other people's property? It is a miserably paid profession and a man must keep up-to-date by subscribing to technical journals so that he may take advantage of other people's experience and it takes all a man can afford to keep up. The mention of Doctors in Henry Wright's letter (5th Jan.) makes me think of efficiency. If the average engineer gave no more efficient service than some of the doctors he would soon be let out.

The hot eccentric strap in J. W. C.'s letter (5th Jan.), I should have slowed down and brought it back with oil, but maybe they had a crabby old captain who couldn't be reasoned with. I was with a very clever chief who took the same course with a hot strap, he played the hose on lightly, and a liberal application of oil and escaped without damage, the ship was in danger and couldn't be stopped. If all who are interested in Dominion Wide Certificates write to you, you will need to enlarge your journal considerably.

Robert Gascoigne

The Editor,
"Power House:"

I note with much interest your letters on Dominion Wide Certificate in Nov. 5 and Dec. 5th issues of Power House. It is a matter that should interest every engineer in Canada and now that you have started the ball rolling I would like to see every engineer take hold and if possible get Canadian certificates and not Provincial. Why should an engineer who is a Canadian or British subject capable of passing an examination of a certain standard and proving his qualification, and is operating or has charge of a plant in Nova Scotia, not be capable of running the same plant in B. C., Ontario or any other province?

While I hold the certificate and the position of a first-class engineer in Ontario, yet I think that any engineer who has passed an examination of the same standard as I have should be entitled to operate in Ontario no matter where he passed his examination. I think Mr. Goepel's arguments against the subject could be easily overcome. Our hoisting engineers' examination will thoroughly overcome the logging difficulties of which he speaks, and is entirely separate and independent of stationary engineering. It is also a difficult examination to pass for any one who is not familiar with the operation of hoisting equipment. Any engineer who can handle locomotive cranes, hoists, etc., in Ontario, would be able to handle logging equipment in B. C.

Mr. Goepel also seems to think that B. C. has the strictest examinations and examiners in Canada, but I want to tell him that if they are any more difficult than our first-class exam, then nobody will get them but university graduates. Our examiners are fair and impartial, and you have to qualify for the grade you want.

I would say "Let us have Dominion Wide Certificates."

C. J. Morrisson,
Walkerville.

STEAM PIPE EXPLOSION FROM WATER HAMMER ACTION

The Board of Trade have issued, under the provisions of the Boiler Explosions Acts, 1882 and 1890, a report of a preliminary inquiry made by I. F. Blenkinsop, one of their surveyors, with regard to the circumstances and cause of a steam explosion which occurred on August 25, 1920, at the New Hall-lane Mill, Preston, in the occupation of Messrs. Paul Catterall, Son and Co., (1920) Limited. Fortunately no fatal result ensued, but one man was somewhat scalded.

The pipes, which were new, having been made by Messrs. John Spencer, Limited, Globe Tube Works, Wednesbury, the previous March, formed part of the main steam line leading to a new engine which had recently been installed at the mill. The steam line was made up of a number of lap-welded steel pipes, 9-in. internal diameter, 5/16 in. thick, with screwed-on flanges, 16-in. diameter, jointed together by twelve ⅞-in. bolts, having a pitch circle 14-in. in diameter. The mean distance from the boiler-house to the engine stop valve was about 80 ft., but with the several horizontal and vertical leads, the total length of steam pipe used was approximately 146 ft., Hydraulic tests were witnessed on the pipes to a pressure of 280 lb. per square inch by an inspector of the Vulcan Boiler and General Insurance Company, Limited, at the maker's works, in March 1920. At the time of the explosion, the new engine, boilers and economzers were insured by this

company, but the steam pipes were not covered by the policy.

Two lengths of steam pipe in the engine house were damaged by the explosion; one contained a longitudinal crack at the weld, open at its widest part, ½ in., and 9 in. in length, and the other a ragged hole, 7 in. from the weld, which had a maximum width of opening of 4 in., allowing steam and water to escape into the engine-house; the pressure of steam being about 140 lb. per square inch.

The explosion was due to water hammer action.

In his report to the Board of Trade, under the heading of "General Remarks," Mr. Blenkinsop writes as follows:

"The work carried on at the New Hall-Lane Mill is cotton spinning. Steam is supplied by three Lancashire boilers, each 30 ft. in length, by 8 ft. 6 in. in diameter, at a pressure of 180 lb. per square inch, and conveyed to the engine by a long range of lap-welded steel steam pipes, 9 in. in diameter. Before steam reaches the engine stop-valve it passes through a separator, to which is connected a steam trap, suitable for a pressure of 180 lb. per square inch. The power is distributed to the mill by means of rope gearing. A new engine built by Messrs. Yates and Thom, Blackburn, was recently installed, when new steam and feed pipes were fitted; the work was carried out by Messrs. Dryden and Son, Preston, whose workmen were still employed on the plant at the time of the explosion.

"On August 20 and 21 satisfactory preliminary trials of the engine were made. On Sunday, August 22, steam was used for the barring engine to place ropes on to the driving pulley, when it was noticed that the steam trap connected to the separator was not working properly, and it was decided to fit another trap. As a temporaray measure, the defective steam trap was removed and a straight-through drain valve and pipes, 1-in. bore, were fitted, the pipes being led through the engine house door, discharging into the mill yard. These alterations were completed on Monday, August 23, when a final trial of the engine, under load, was made, preparatory to supplying power to the mill by the new plant on the following morning. This trial was quite satisfactory.

"At the end of the trial the mill engineer found that he could not shut the engine house door without removing the end length of the temporary drain, which he removed, and as the discharge from the drain came into the engine house, he closed the drain valve, leaving it closed overnight. In mill practice the boiler stop valves are left open for heating purposes, steam traps being fitted to prevent accumulation of water in the steam pipes; the steam pipes were formerly well covered with non-conducting material to prevent condensation. In this case the work of covering the new pipes had only commenced, so that the drain valve being shut water would collect in the steam pipes overnight.

"The mill engineer states that his first action on the morning of the explosion was to open the engine house door, connect up the end length of drain pipe, and open the drain valve. The engineer, who was accompanied by the engine-builders' foreman, states that water came out of the drain pipe full bore. He then proceeded to oil the engine prior to starting, and states that about 7 minutes after opening the drain valve he heard a loud rumbling noise which was followed by a rush of steam. At this time there were present in the engine house, the mill engineer, the engine-builders' foreman and Thomas Scohill, a laborer, who was employed assisting the pipe coverers, and was injured by the escaping steam and water.

"The damaged pipes were taken down and repaired; the pipe which opened out at the weld was fitted with a patch 2ft. 3in. long, by 12in. wide and ⅜in. thick, riveted only ⅝in. rivets at 2in. pitch. The edges of the patch were electrically welded. The other pipe was repaired in a similar manner, the patch being 2ft. long by 12in. wide and ⅜in. thick. After being repaired, these pipes were hydraulically tested to 270 lb. per square inch and replaced. A new steam trap has since been fitted, which is working satisfactorily."

Mr. Carlton, engineer surveyor-in-chief to the Board of Trade, in his concluding "observations" says: "The conditions obtaining at the time of the explosion clearly point to the action of 'water hammer' as the cause; and it would appear that those in charge of the plant were not apparently aware that the clearing of water of condensation from a range of steam pipes whilst in open communication with the boiler is a most dangerous practice, and in this particular case the shock of 'water hammer' was most violent."

BUSINESS PAPERS EXTREMELY VALUABLE

IT WAS the reading of a business publication that inspired Henry Ford to quit the farm and seek employment which would help him to build a "horseless carriage" such as he then read about. It was by reading a business publication that George Eastman got the idea of establishing what has become by far the greatest establishment of its kind in the world. It was the reading and studying of business writings that started Frank A. Vanderlip on a career which landed him in the presidency of the largest national bank in America. Edison reads more business periodicals and books than perhaps any other man in America; he assured me that he couldn't afford not to.

Cyrus H. K. Curtis once told me, continues an editorial in Forbes Magazine, that he first conceived the idea of creating the Saturday Evening Post when, as a youth, he read a story about a young man who achieved dazzling success in business. It was reading and studying the business achievements of John D. Rockefeller that fired James B. Duke with ambition to become in tobacco what Rockefeller had become in the oil industry.

Only the other day a salesman of one of the many business "courses" now in vogue, told with great gusto that he had just sold his "course" to the president of a very large railroad, Daniel Willard, of the Baltimore & Ohio. J. Kindleberger, the famous paper manufacturer, tells how the reading of a business book caused him to organize what became a very successful enterprise.

Recognizing the infinite value of business books, "Forbes" has decided to open a new department to encourage the reading and studying of them by those who are ambitious to make headway in the world. As one means of emphasizing the benefits which can be derived from business books, they are offering $250 in prizes for letters answering the question, "Which Business Books Have Helped You Most, and How?"

It has become not uncommon, concludes the article, for employers to get a line on the kind of reading done by employees being considered for promotion. I once heard of an employer who made an excuse to visit the home of an employee whom he was thinking of promoting, but when the only reading matter within sight was a popular weekly and second-rate fiction, the employer concluded that he had better promote someone who devoted at least part of his spare time to reading periodicals and books calculated to widen his knowledge of his business and broaden his mentality.

The man who reads this story is to be congratulated, because he too is a reader of a business paper, and is thus building upon a solid foundation.

ANNOUNCEMENT

The Bailey Meter Company, Ltd., have now established Canadian offices at 179 Delorimier Ave., Montreal, and will manufacture Bailey meters in Canada. The Canadian branch will be closely affiliated with the parent company in Cleveland, Ohio. Mr. John Bryson, who has been in charge of the meter and instrument department of Peacock Bros., Montreal, will be Vice-President and General Manager of the Canadian company.

After being closed for over a year, the factory of the Central Spring Co., Oshawa, Ontario, started on January 9th, to get their factory in shape to resume operations as soon as possible. They will employ 20 men at the outset and expect in the very near future to have a full complement of 70 men working.

The "Lagonda" Reseating Machine, Motor Driven with Emery Wheel

Boiler Efficiency

Demands the Use of

LAGONDA EQUIPMENT

"Lagonda" Boiler Tube Cleaner

1. THE LAGONDA RESEATING MACHINE: the most effective means known for removing scale from tube ends and caps. It removes obstructions and leaves the surface bright and polished so that the cap fits perfectly. Insures a steam and water-tight joint. Machine consists of an emery or carborundum cloth wheel driven at high speed by a motor.
2. LAGONDA BOILER TUBE CLEANERS: the simple, economical and sure way to keep boiler tubes free from scale. The use of a Lagonda Cleaner removes all deposits and the tubes are then practically as good as new. Cleaners are water, air or steam driven and designed for use in all sizes of tubes over 2-inch diameter. Made in types for every condition.
3. LAGONDA AUTOMATIC CUT-OFF VALVES: the safeguards of the boiler room. They are essentially safety valves, protecting life and property. Designed to close automatically in case of an abnormal flow of steam from either direction. From Asia to Alaska they boost boiler efficiency and eliminate accidents.

"Lagonda" Automatic Cut Off Valve

Valuable Accessories

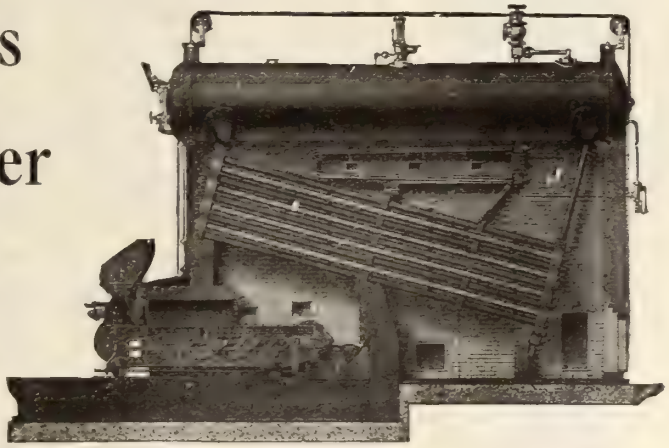
TO THE

"B & W" Steam Boiler

Combine LAGONDA Boiler Accessories with a "B. & W." STEAM BOILER and you have a boiler room with production ability second to none.

"B. & W." STEAM BOILERS set the world's standard for boiler efficiency. More than 50,000,000 H.P. are now in use in every country, on land and sea.

This place of leadership is the recognized tribute to a design devoid of all unequal strains—a design easy to clean, easy to erect and possessing sufficient durability for many years of service.



"B & W" Patent Water Tube Steam Boiler with Superheater and Mechanical Stoker

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

COFFIN SLUICE GATES & VALVES

Selected for Important Duty

The picture shown here gives an instance of the important duty assigned to coffin equipment, which is a photo of three 3 by 5-ft. sluice gates supplied to the Nova Scotia Power Commission for their St. Margaret's Bay Development. Coffin equipment is thoroughly dependable. The Coffin line includes:

Electrically, Hydraulically and Hand-operated Sluice Gates, Gate Valves and Butterfly Valves; Check Valves, Flap Valves, Foot Valves, Shear and Slide Sewer Gates, Automatic Sewage Regulators, Fire Hydrants, and all such other devices for the control of water.

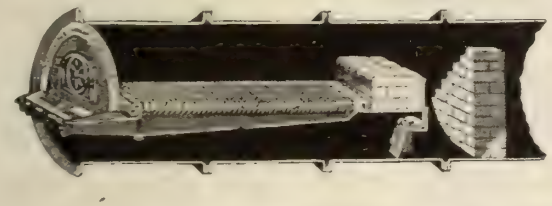
Why Burn Expensive Fuel—



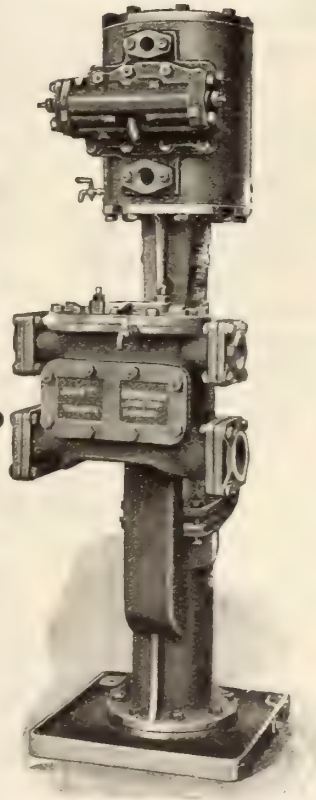
When the
TURBINE (Patent) Furnace
Effectively Burns Coal Slack?

Turn to this method of heating and save many dollars a year. The highest form of fuel economy. For Externally Fired or Internally Fired Boilers. Burns coal dust and low grade fuels effectively. Consult us, now, about installing one.

Manufactured by
The Turbine Furnace Co., Ltd., London, England

Sole Canadian Agent:
PERCY A. GOEPEL
525 Pender St., W., Vancouver.

Minimize Pump Depreciation with a HEPBURN Patent Vertical RAM PUMP



In a Vertical Ram Pump of this type there is little wear on the cylinders. The weight of the piston and ram is taken by the water pressure and does not unevenly wear the glands and cylinders.
This pump will handle high temperature water at high steam pressures. There is a Minimum of packing required, ensuring a Minimum Leakage; Automatic Draining; No Tappets or Levers; All Parts Accessible. It runs full stroke even at slowest speed and occupies little space in the Power House.
We also make Cranes, Castings and Forgings. We will be pleased to have your business. You will be pleased that you gave it to us.

Belting That Has Endurance

Belts are expensive. The item of Belt replacements might run into good sized figures in some factories. The time lost in factory idleness while poor Belts are being repaired or replaced is worth more than the Belts. Buy the *Best*—because they *Last* longest and save *Time* as well as *Money*

SITUATIONS WANTED

STATIONARY ENGINEER DESIRES POSITION as engineer or fireman. Holds second class certificate, 20 years experience. Apply to Box 151121, Power House.

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.

EQUIPMENT

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House. H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand: electric machinery repaired; we also buy motors. Apply, mentioning Power House. The Electrical Engineering Co., 122 Wellington West, Toronto.

POWER HOUSE

Solves the Problem

It is a dominating factor in maintaining power plant efficiency in equipment and service.

Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

TWO ISSUES PER MONTH
TWENTY-FOUR PER YEAR

TWO DOLLARS

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS WANTED—MALE

ENGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

STATIONARY ENGINEER, SECOND-CLASS, requires position. 10 years experience with steam, motors and generators, refrigeration, ammonia and carbonic acid systems, heating systems and hydraulic first-class references. Apply Box 5122, Power House.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821, Power House. p.2.h.

INSTRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any province, stationary or marine. Terms and particulars on application. Box 13921, Power House. Ph2

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House, P2H

STATIONARY ENGINEER—SECOND CLASS, requires position, ten years' experience of steam generation, refrigeration, cold storage and electric generation, thoroughly experienced with heating systems and hydraulics and all classes of stationary engines, used to large plants, good references. Apply to Box 5122. P.3H.

FOR SALE—45 K.W. Edison D.C. 125 V. Dynamo, 1050 R.P.M., with rheostat and spare armature. In perfect condition and can be seen running up to about end of January. Board of Trade Building, Montreal. Price $250. Apply Superintendent.

A Real Service To Engineers

Mr. John H. Forsyth, Chief Engineer of the DeLaval Co., Peterboro, says of POWER HOUSE:

"The whole thing can be said in a few words—'Power House' delivers the goods and no engineer who has the interests of himself and his employer at heart should be without it."

Many men have paid thousands of dollars to get necessary information that would contribute to their success. You, as an engineer, or power plant employee in any capacity whatsoever, will be interested in this fact, that your expenditure for knowledge need not be excessive. You can have it fresh, twice a month, twenty-four times a year, for two dollars. For "POWER HOUSE," the Power Plant Journal of Canada, positively delivers the goods—edited by Canadian men with the Canadian viewpoint well in mind. Do you know that hundreds of engineers have told the publishers that POWER HOUSE has been frequently of inestimable value to them, solving their problems, guiding their vision, steadying their attitude, and qualifying them for bigger jobs, increasing their earning power; in a word "POWER HOUSE" shortens the way to success in a very practical and continuous way to the man who really cares and is willing to come across and take what "POWER HOUSE" has to offer.

POWER HOUSE,
The MacLean Publishing Co., Ltd.,
143 University Ave., Toronto.

Please enter my name as a regular subscriber to the POWER HOUSE Journal, commencing at once. I am enclosing $2 to pay for my subscription for the first year. (Write address plainly.)

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

HINTS TO BUYERS

'Bishop's Adamant' Gauge Glasses

Will resist all Steam Pressure and Variations of Temperature.

REFLEX GAUGE GLASSES

Annealed and Hardened for
LOCOMOTIVES, STEAM WAGONS, MARINE AND STATIONARY BOILERS.

Adamite Gauge Glass Rings. Glass Tubes and Rod

S. & C. BISHOP & CO., St. Helens, Lancashire.

$842.50 Saved Per Year By A Green Chain Grate Stoker

The Standard Tire Company installed a Green Chain Grate Stoker at their plant in Willoughby, Ohio, and report a saving over previous firing methods of $842.50 per year in their cost of steam.

Green Engineers will be glad to tell you how they make savings in the cost of steam. Write Dept. X for full information.

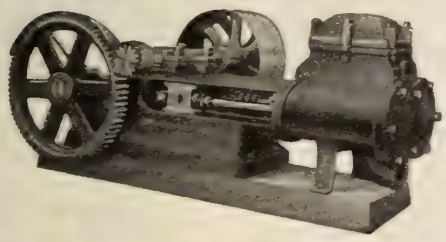
EAST CHICAGO, INDIANA

STEAM AND POWER PUMPS FOR every service.



THE SMART-TURNER MACHINE Co.
LIMITED
Hamilton - Canada

The Simplest and best cleaner on the market is

PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.
Manufactured by
PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.
Eastern Office: 71 Fulton St., New York.

LADD WATER TUBE BOILER

LADD
WATER TUBE BOILER
COMBINES PERMANENT ECONONY OF OPERATION WITH UNUSUAL ADAPTABILITY TO ANY INSTALLATION REQUIREMENTS.

An economy when buying machines or supplies

Because the Canadian Fairbanks-Morse Co., Limited, is "Canada's Departmental House for Mechanical Goods"—selling everything your business needs in the highest-grade machinery and supplies—it offers you all the savings of grouped orders and bulk shipments.

And this economy of centralized purchasing brings with it an assurance of dependable quality and sound values because the Canadian Fairbanks-Morse catalog lists the products of the foremost manufacturers.

Furthermore, each department is under the supervision of experienced men who know how best to fulfill your exact requirements.

Make our nearest Branch your buying centre and our catalog your guide to the most reliable mechanical goods.

ELESCO

SUPERHEATERS
ARE MADE IN CANADA

Obtaining Increased Boiler Capacity at a Low Cost

With its 1,000 h. p. boilers working to the limit of their capacity, and with no floor or building space available for additional installation, a plant still needed 250 boiler horse power.

A new 250 h.p. boiler, with brick work and setting, but not including floor or building space, additional auxiliaries, etc., would cost $11,000.

Investigation disclosed that the capacity of existing boilers could be increased 25%, or 250 h.p., by the use of 150° superheat, through the installation of Elesco Superheaters; the cost, in this instance, delivered and erected being $6,000.

Equivalent boiler capacity increase, obtained through Elesco Superheaters, at a saving of $5,000.

No additional floor or building space required.

Little or no more fuel is consumed at the increased load than formerly; steam lines and engines are protected from the dangers of water hammer; entire plant operates more effectively.

Let our engineers assist you in analyzing your conditions to determine just what it will cost you to effect an increase in capacity by installing Elesco Superheaters in your boilers.

Morrison
RECORDING
Pressure Gauges

remove the worries of "trying to keep track" from the shoulders of the busy executive.

To the plant superintendent Morrison Recording Pressure Gauges are a simplified form of cost accounting. To the fireman they are a true guide to economical firing. They are indispensable to both.

All steam pressure variations that occur for every hour of the day are indicated with precision on easily read charts. The fireman can tell immediately when more coal is required or other attentions needed. Consequently all waste is cut to the lowest figure.

In choosing Pressure Gauges always specify **"Morrison's"**. There's nearly half a century's experience at your disposal. Write us for further particulars.

Other lines we manufacture are Valves, Injectors, Ejectors, Inspirators, Clocks, Whistles, Bells, Pipe Fittings, Lubricators, etc.

THIS CONCRETE DAM
successfully met a severe test

CANADA is justly proud of her "white coal." The development of the Dominion's water power has employed the highest skill of the engineering profession—and in this development concrete and reinforced concrete construction have played an important part—both as regards publicly-owned and privately-owned water rights.

Our illustrations are from photos of the Southern Canada Power Company's plant at Drummondville, Quebec.

The top view shows the completed dam—and the arrow points to the location of the Power House.

The lower view illustrates the splendid resisting qualities of concrete. The breaking up of the ice nine days before the completion of the work unexpectedly flooded the dam; yet the structure was uninjured by the severe strain thus suddenly placed upon it.

LUNKENHEIMER
"Duro" Blow-off Valves

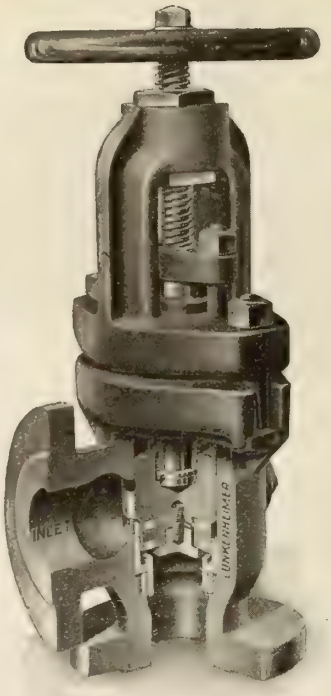

Fig. 897, Flange Ends.
Fig. 896, Screw Ends.

"Duro" Blow-off Valves prevent heat waste in blow-off lines. They remain tight under extreme operating conditions because they are not only made of wear resisting materials, but their design is such that the usual causes of leakage are eliminated.

The piston shaped disc secures a gradual release of the water due to its travel in the cylinder above the seat before full open position is reached. And when closing, the seating surfaces are automatically cleansed by the fine stream of water forced past the disc as it travels through the cylinder casing before seating. This action also minimizes wire drawing of the seat.

"Duro" Blow-off Valves contribute to efficiency and economy in plant operation and meet every blow-off requirement. Sizes 1¼ to 3 inches, in Iron Body Bronze Mounted Pattern for pressures up to 250 pounds.

Specify "DURO" BLOWOFF VALVES and insist on their installation.

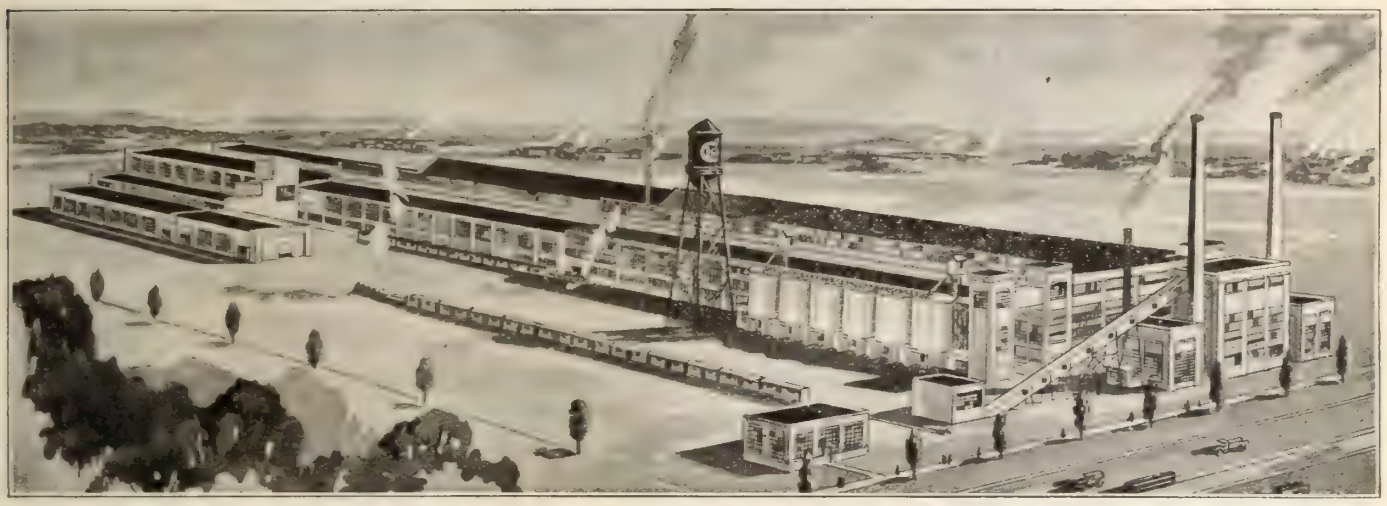
Jenkins Valves



The Libbey-Owens Factory at Hamilton Equipped With Jenkins Valves

Fig. 300. Jenkins Brass Gate Valve Type "K"

The Libbey-Owens Sheet Glass Co. Limited fully appreciate the importance of dependable equipment in the production of their "Made-in-Canada" Window Glass.

Knowing what an important part satisfactory, trouble-free valve service plays in efficient operation they selected Jenkins Valves as the most dependable and as guaranteeing that continued operation which precludes expensive replacements and "shut-downs" for repairs involving loss of time and labor.

Jenkins Valves are dependable and trouble-free because they are made by experts from the very best brass, iron or cast steel and **tested for maximum service before leaving the factory.**

There's a type and a size for every service everywhere. The complete line is fully pictured and described in Catalog No. 8, free on request.

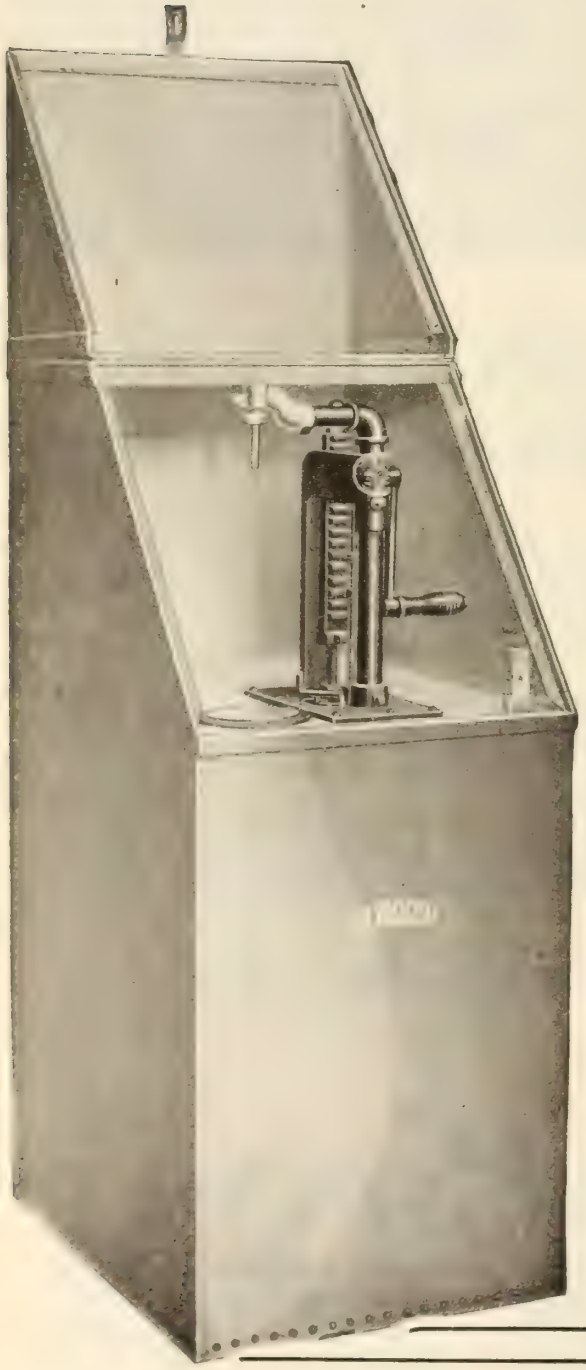
Get Better Lubrication at Less Cost

Install Bowser Oil Handling Equipment

Incorrect lubrication will take its toll of your machinery slowly but surely. Undue depreciation is bound to result from the friction caused by gritty oil. And no matter how good the oil you buy, you cannot have correct lubrication unless it is *kept clean.*



By storing oil in Bowser leak-proof and dust proof Tanks, you will keep *your* oil clean and give better lubrication to your machinery. The Piston-Type Pumps deliver exactly the amount required directly into the distributing container, eliminating waste. Bowser centralizes your oil storage, making it easily accessible. The safety of Bowser is also an important element to consider.

Not once in 36 years has Bowser Equipment started or contributed to a fire.

Whatever your requirements, there is a Bowser to meet them. Ask us.

Do You Pack Both Ends of the Pump With the Same Packing?

Greater efficiency and economy can be secured by using in each service the packing best adapted to that service.

THE STEAM END

In addition to friction heat this service must contend with the high temperature of the steam, causing any packing not thoroughly heat resisting to quickly char and burn.

"PALMETTO"

is a packing that high temperature cannot affect and its perfect graphite grease lubricant prevents it from hardening, and keeps the rod well lubricated.

THE WATER END

Most of the packings for hydraulic pressures create excessive friction, swell, and so bind as to cause the pump to short stroke.

SQUARE PALCO PLAITED PACKING

will not swell and is made frictionless by reason of each single strand carrying a heavy graphite lubricant, thus preventing wear of both rod and packing.

May we send you working samples of these packings to prove the economy of their use in steam pumps.—No charge.

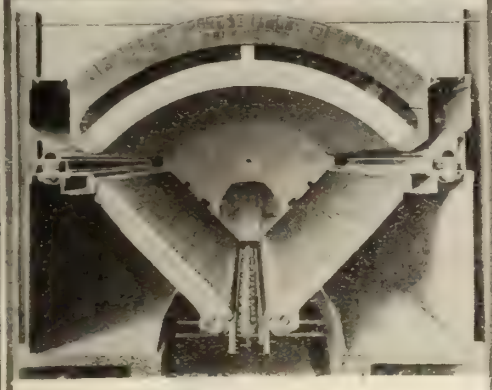
Cutting Coal Costs

For 44 years Murphy Furnaces have been saving coal and lightening labor for thousands of users in every section of the country. Many reports are being received such as this from a City Hospital saying that they *saved* from *seven to ten tons of coal per 24 hours* over previous hand fired conditions.

Here's why the Murphy is a fuel saver. It feeds the coal without opening the fire doors. The admission of cold air in large volumes is thus prevented; economy is secured and the life of the boiler is prolonged. The Murphy Furnace goes a step further. The fire is cleaned and the refuse removed automatically. This is a continuous operation and can be regulated to meet any condition. Every part of the fire chamber is visible and accessible. There is no periodic dumping nor drawing out of ashes, clinker, and incandescent fuel and coke, with resultant lowering of furnace temperature and steam pressure.

A request from you brings our Catalog H-2 describing the Murphy Furnace in ful



Factors Back of Every Installation of MURPHY FURNACES

Natural Draft—on everything except the most extreme peak loads. Will double the output of your boilers without one penny for draft.

Standard—The Murphy Furnace is standard in design. In many instances the new features that have been developed may be applied to Murphy Furnaces now in use.

Smokelessness—The Murphy Furnace is designed to afford perfect combustion. The arch insures high furnace temperature which means that the air is preheated and admitted exactly where and when needed to give maximum efficiency.

Automatic Operation—The amount of fuel supplied may be regulated while in operation. Every detail for keeping a perfect fire is provided in the design and construction of the Murphy Furnace. The coal is supplied—the fire distributed evenly—the ash removed—continuously and automatically.

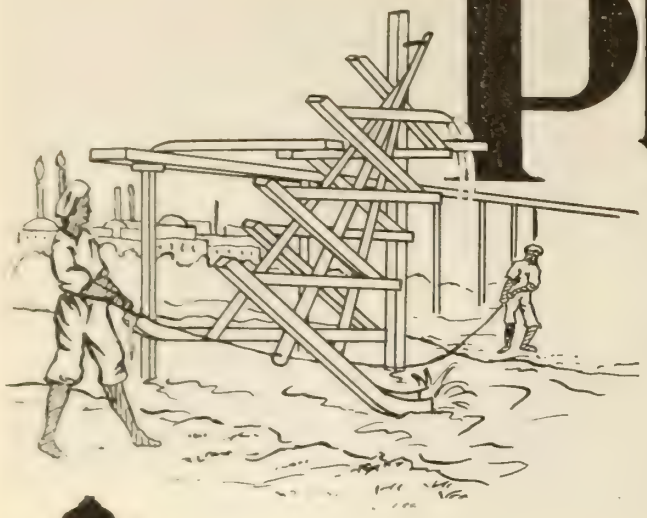
PUMPS



One of the Most Curious of Ancient Pumps

The ancients had many peculiar schemes for making water run uphill, but none of them more peculiar than the Indian Rocking Pump. Two men and a rope furnished the "power." The water was rocked upward from one gutter to another, until it was finally emptied into a long trough and carried to the land.

To say the least, the Rocking Pump was indirect and circuitous. Unlike modern American-Marsh Pumps—**which go straight to the heart of difficult pumping problems**—it was slow, wasteful and roundabout.

Write for American-Marsh Bulletins

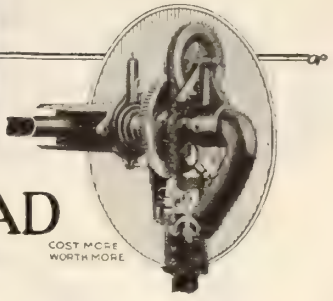
Practically Complete Elimination of Condensate Obtained



DIAMOND
VALV-IN-HEAD
SOOT BLOWERS

COST MORE WORTH MORE

One of the most important results of the use of the Valv-in-Head soot blower is the practical elimination of the possibility of water entering the portion of the soot blower inside the boiler. With all other blowers, the valve is located anywhere from 2 to 15 feet or more from the head. This means that condensation will inevitably take place when the valve is opened and steam is admitted to the cold line. The water thus formed is driven through the soot blower head and into the blower element.

In addition to the condensate thus formed in the line, a more serious possibility is that a small leak in the valve will cause water to form in the pipe before the valve is opened. When this occurs a solid column of water may be built up in the riser pipe and carried over into the boiler when the valve is opened.

With the Valv-in-Head system, any condensate in the main supply line is discharged through the drain pipe before blowing begins. There is, therefore, no water below the valve which can be carried into the blower head and the radiation area in the head itself is so small as to be negligible. Hence we have practically complete elimination of condensate from the blower element.

Constructional Features

The valve is made with Monel metal disc and seat. Both the stem and its retaining nut are made of nickel steel. In order to secure extra hardness which insures durability, the end of the stem is heat treated. Action of the cam and trigger are positive, assuring complete opening of valve at each revolution. Trigger, cam and clamps are steel, spring is chrome vanadium.

Ball thrust bearings—a new feature on soot blowers — are provided to relieve friction caused by thrust of unit. Special patented construction makes head full floating, permitting movement of unit in any direction as boiler walls expand or contract.

Valv-in-Head construction therefore means increased length of service of boiler tubes, complete removal of soot with no gummy deposits left behind, and long life of soot blower elements, with a reduction in annual blower maintenance charges from 25 to 50 per cent. This is only one of eleven important advantages of Diamond Valv-in-Head soot blowers. Every boiler needs a mechanical soot blower and you will save money by buying the best.

Diamond Valv-in-Head Soot Blowers are described and illustrated in detail in our new Bulletin 287. Write for your copy.

"The Drop-Forging People"

78 Thorold Road St. Catharines, Ontario

Four and six inches of Nonpareil Corkboard make up the insulation in the plant of the Birmingham Ice and Cold Storage Company, Birmingham, Ala. This view shows one of the apple storage rooms.

How Long Is Two Months?

"Plenty of time before spring." Is there? Sixty days go pretty fast. Are you preparing for warm weather by insulating your rooms now, or are you putting it off to be caught in the last minute rush?

The best way to be sure that your rooms will be *ready* is to get at them now, in your slack season. And the best way to be sure that your rooms will be *right* is to use

NONPAREIL CORKBOARD INSULATION

For All Cold Storage Rooms

Nonpareil Corkboard has remarkably low heat conductivity. It is non-absorbent of moisture and does not deteriorate in service.

Nonpareil Corkboard is reasonable in cost and, equally important, it is the least expensive insulation to erect. Being uniform in quality and dimensions, it is ready to use without sorting and trimming. Straight edges and square corners make tight joints and eliminate waste of time, labor and material.

Experts will assist you with your plans. Skilled workmen will erect your insulation or detailed instructions will enable you to do it yourself. There is no question of results with Nonpareil Corkboard Insulation.

Write at once for the 152-page book, "Nonpareil Corkboard Insulation." You will appreciate its detailed and helpful information on cold storage construction. Sent free on request.

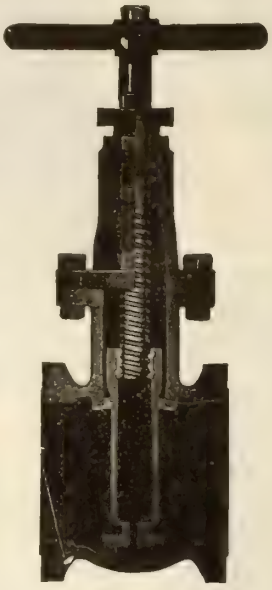
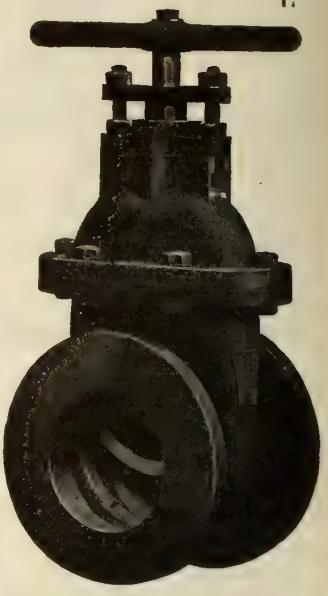
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.



If you have been using them, we are confident that our satisfaction will bring us your repeat orders These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.



When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

"New Truths and Old Fallacies"

WEARING QUALITY

We mentioned previously the fact that the small particles worn from the surface of a Magnolia lining by the microscopic cutting edges of the shaft are usefully expended in filling in the interstices of the shaft, thereby imparting to both shaft and bearing a hard, glassy finish.

After this conditioning the wear practically ceases, or progresses so slowly that often it is hardly appreciable after ten years or more of service.

The conditioning of a bearing is its crucial period, but in the case of Magnolia it does not seem to matter even on a rough cast bearing, so promptly does it adjust itself.

We have records of Magnolia bearings on ice machine engines that have been in service equivalent to over thirty years, based on ten hours a day run, and which, from last accounts, were still running in good shape.

We have a number of records of twenty years or more of service, and reports of bearings running five and ten years, and still running, are too frequent to excite special comment, and we are in constant receipt of splendid testimonials.

During the first period of conditioning a bearing, there is naturally some rise in temperature, but with a Magnolia bearing this never reaches the danger point, and gradually assumes a low fixed temperature.

Both Professors Smith and Goodman state that Magnolia's best qualities show when subjected to heavy pressure. This cannot be said of most other babbitts because the grinding effect of the shaft causes rapid wear and heating.

CURTIS

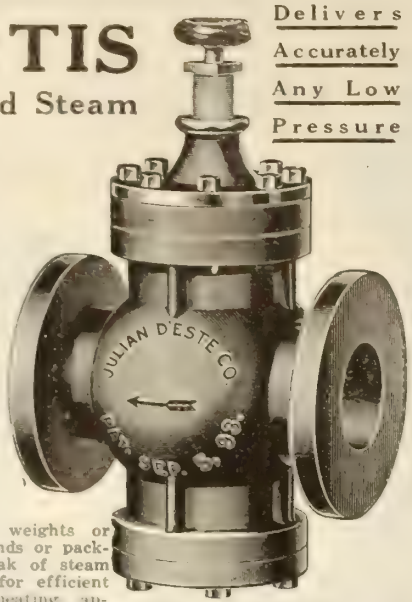
Improved Steam

Pressure Regulator

Delivers Accurately Any Low Pressure

A compact self-contained Regulator suitable for any boiler pressure. It delivers accurately and uniformly any lower pressure from one to within a few pounds of the initial pressure.

It has no levers, weights or projections; no glands or packing; no drip or leak of steam or water. Use it for efficient service on steam-heating apparatus, slashers, jacket kettles, air or water pumps, pulp mills etc.



The Improved Steam Pressure Regulator is a lock valve, very simple and sensitive. Send for descriptive pamphlet.

Money is Getting Cheaper!

Money rates are down, the accumulation of funds looking for investment is climbing. First class bond issues no longer command the high rates of interest prevalent in 1921. This unquestionably means that industrial securities will have their chance ere long and more and more capital will look to business for its employment. Undoubtedly an increase in the general business of the Country will follow.

Is your plant in good shape? Particularly, are your Boilers modern, efficient and economical?—or are they steam wasters, coal devourers and always longing for the repair gang? Just because you don't see your Boilers at work very often—don't overlook the big opportunities there are for money savings in this department. We make modern Boilers of all types for power or heating, our workmanship is unsurpassed, and our prices are certainly low enough to-day to interest you.

The spongy component accounts for the remarkable efficiency of Asbesto-Sponge; the asbestos component explains its great strength and long life.

Dead air—
first aid to live steam

WHEN your steam pipes show symptoms of falling pressure and high external heat, cover them with Johns-Manville Asbesto-Sponge—the insulation which develops the dead air principle to its fullest extent.

The base of Asbesto-Sponge is asbestos, with which is mixed a spongy material whose countless dead-air cells form a natural barrier to heat. This insulating property is greatly strengthened by the laminated construction of the covering, for between the layers are dead-air spaces which also check heat loss. But it is not enough that this insulation should be the most efficient on the market.

The fibres of asbestos, felted and bonded together with the sponge into tough, resilient layers, assure strength and protection. Asbesto-Sponge does not crumble under vibration, and it stands up under the hard knocks which prove disastrous to insulations of the moulded type.

In many cases Asbesto-Sponge actually outlasts the pipe it covers.

The Gas and Oil Engine In The Power Plant

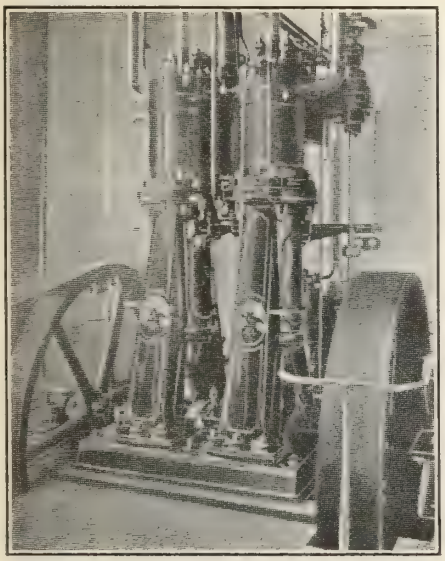
In This Article a General Description of Three Different Types of Four-Cycle Full Diesel Engines is Given

By T. H. Fenner

THERE has been a steady development in the use of the internal combustion engine for stationary purposes in the past few years, in the United States and Canada, while in Europe development for both stationary and marine purposes has been steadily carried on. The engines in use in this country are practically all of British, or European or American build, although at least one company in Canada has built a Diesel to their own designs, which has been described in these columns on previous occasions. This engine was also exhibited at the Toronto Exhibition of last year, and was the subject of great interest to a large number of visitors.

Gas engines, as distinguished from gasoline, or the crude oil type of engine, are found in this country chiefly in steel works, where the waste gases from the blast furnace are used as fuel, after passing through suitable washers and scrubbers. There are some fine examples of this type in the Algoma Steel Co.'s works at Sault Ste. Marie, the installations having been made by the Mesta Machine Co., Pittsburgh.

Gas engines using town gas or producer gas are in very wide use in Great Britain, but this form of power does not seem to have been used in Canada to any extent. There is of course the question of heating which is an ever present one in this country, and which makes in many cases the steam unit the most desirable. However where low grade coal is available, suitable for producer use, and both oil and steam coal are dear there is a possibility of the gas engine with the gas producer filling the need. The writer recalls one plant where a very fine gas engine and producer was installed, in the plant of a convent, which already had a most efficient steam generating and heating plant, and a small ice-making plant. There was absolutely no necessity for making any alteration, excepting that the man who was instrumental in getting the installation approved by the good sisters was in need of money. Needless to say, from one cause or another that engine was never turned over from the time of its installation until

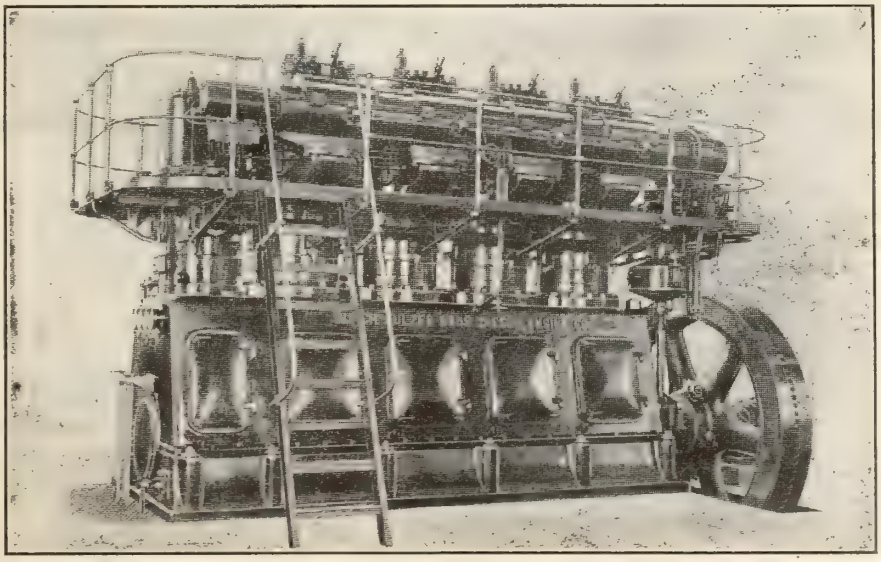


The first Diesel built in America

the writer's knowledge of the plant ended, which was two years after. A new engineer took charge shortly before that who had never seen a gas engine or producer, so it is possible that the plant is still lying idle. The only excuse for mentioning this case is to point out that the final decision on any installation should be the result of long deliberation, and a careful comparison of the possibilities of the various types of power generators. A good type of engine installed in a place where the requirements do not allow it to perform to advantage, gets a bad reputation, which extends in the minds of those immediately in touch with the circumstances, to all others of the same type. The man who sold the gas engine referred to thought more of making that one sale than he did of future sales, and the result was that his first sale was as far as the writer knows his last in the locality.

The First Diesel

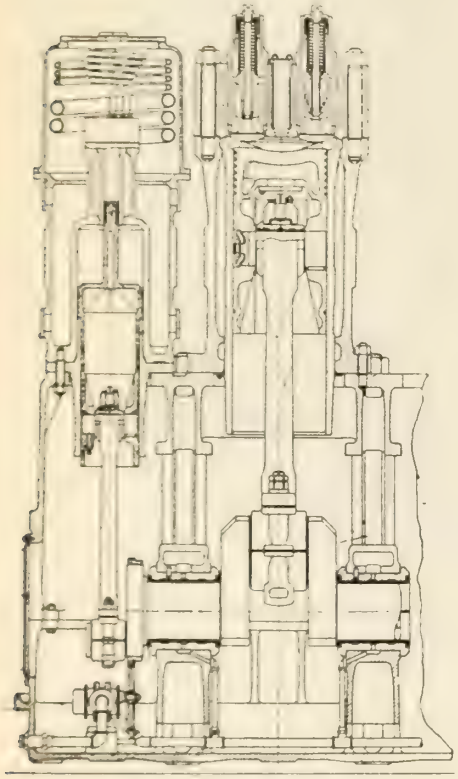
The first Diesel to be manufactured on this continent was made in St. Louis in 1898, by the Busch Sulzer Bros., Diesel Engine Co., and was installed in the Anheuser-Busch Brewery. It is claimed to have been the first Diesel engine to operate commercially in the world. We reproduce an illustration of the engine here, and it can be compared to the later types also illustrated. As in the case of the steam engine, there has been no improvement in the fundamental principle, all the alteration be-



Busch-Sulzer 4-cycle, 4-cylinder, 520 B.H.P. engine

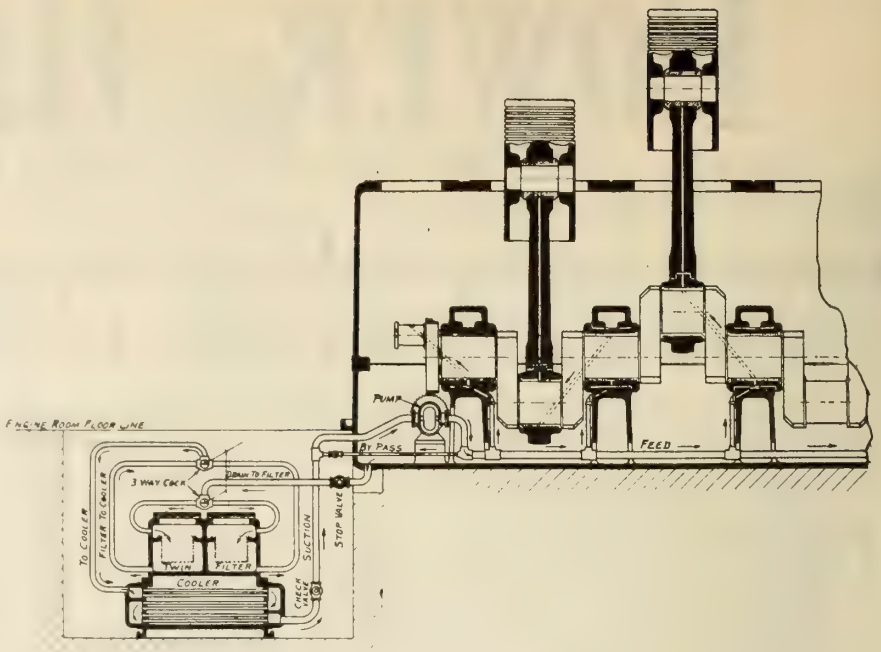
ing in details of design. The first engine was of 60 horse power, on two cylinders. It will be noted that the design of the bedplate columns and cylinders is much more like the steam engine than is the design of the later engines.

The second engine illustrated is a Busch-Sulzer 520 brake horse power Diesel engine, four cylinder single acting 4 cycle type. It will be noticed that in this engine as in all those built nowadays, the crank case is entirely enclosed. This allows for a forced lubrication system, and the reclaiming of all the oil used. The air compressor is shown on the end of the engine, and erected on the common bedplate. These air compressors are either two or three stage, with intercoolers, and while the engine is running a certain amount of air is passed into reserve bottles which are used for starting the engine up.



Cross-section of the cylinder and air compressor. pressor Busch-Sulzer four cycle engine

The bedplate in the engine illustrated which is known as the type B is made in one piece, the main bearing housings being formed by bridges cast between each pair of cylinders. The cylinder liners are made detachable, and are free to expand downwards, being supported at the top end only. The cylinders are water jacketed, and the cylinder casting makes a water tight joint with the water jacket at the top. The pockets for the various operating valves, that is, inlet, exhaust, air starting and fuel valve are contained in the cylinder heads, the valves themselves being of the poppet type. These valves are operated by a cam shaft which works direct from the crank shaft by suitable gearing.



Forced lubrication arrangement Busch-Sulzer engine

Governing is accomplished by means of a centrifugal governor, which varies the time of closing of the suction valves of the fuel pump, thus controlling the amount of oil admitted to each cylinder per stroke.

These engines have been installed in many varied kinds of plants, such as waterworks, electric light plants, and ice plants, in various parts of the world.

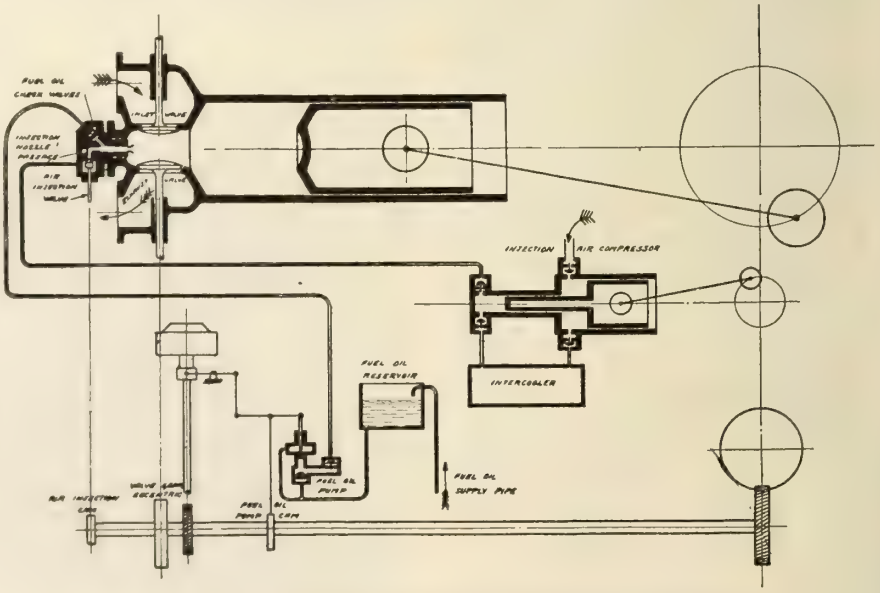
The Allis Chalmers Engine

The engine just illustrated was a vertical type, and as a contrast we show here the horizontal Diesel engine made by the Allis Chalmers Manufacturing Co. This engine is also of the four-cycle single acting type. These engines are made with one, two or three cylinders as may be required, and are adapted to a wide variety of uses.

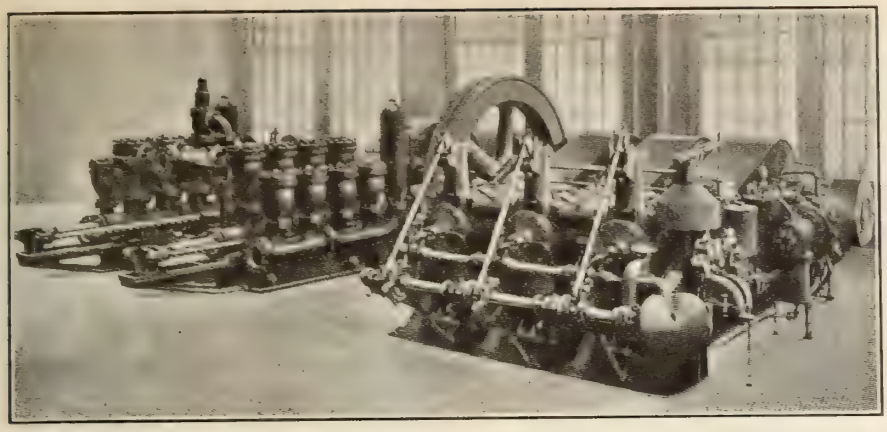
In this engine a separate air starting system is employed, which uses air of a much lower pressure than the air used for fuel injection. This eliminates the use of the storage bottles, and another feature is that the air for starting purposes is distributed through separate valves, the main valves and gear not being brought into play at all for this purpose.

The fuel oil is delivered through an open nozzle into a receptacle, during the suction stroke of the engine. This receptacle is also connected to the air supply, and the air under pressure is admitted to the receptacle after the oil is deposited, and the mixture is forced through an atomising device leading to the combustion chamber at the proper moment.

The governor in this case varies the fuel supply by means of a by-pass which allows a portion of the charge to return to the fuel tank instead of



Schematic diagram of Allis-Chalmers Horizontal Diesel



Three-Cylinder Allis-Chalmers Diesel Direct Connected to Duplex Pump.

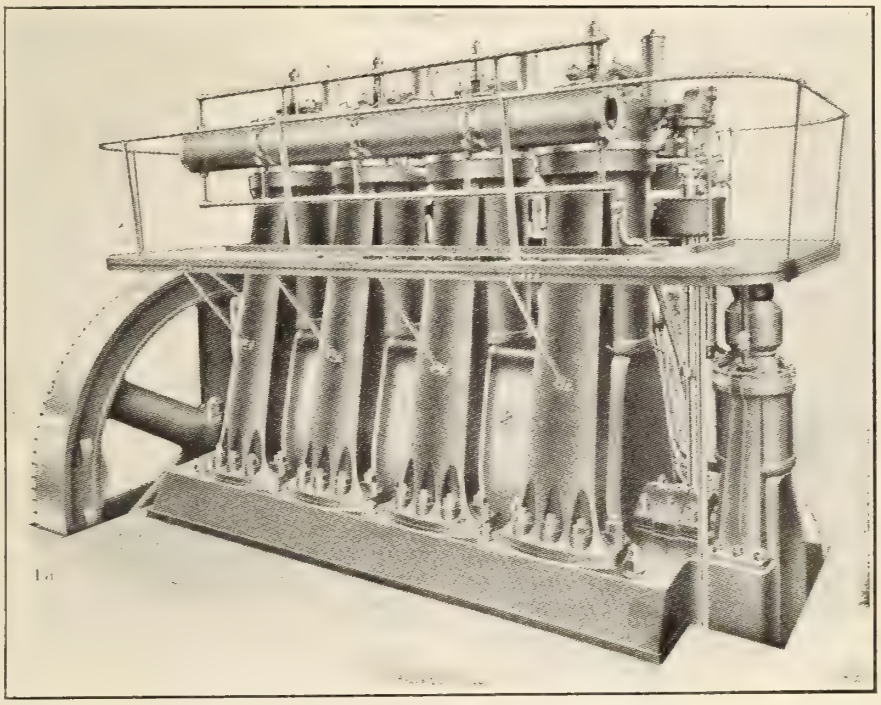
going to the oil receptacle in the cylinder when the engine is running light.

The horizontal form of construction allows a very rigid bedplate, and gives ready accessibility for overhaul and repairs.

The accompanying diagram shows the schematic arrangement of the engine very clearly. The piston is shown on its working stroke, with both inlet and exhaust valves closed. The two stage air compressor is shown, the differential piston accomplishing the two stages of low and high pressure compression, the low pressure stage delivering to the intercooler, and the high pressure stage delivering direct to the fuel chamber.

The arrangement of the fuel oil pump with its by-pass connected to the suction side from the discharge side can be clearly seen, and the arrangement of cam shaft and cams for operating the governor, inlet and exhaust valves, air injection valve, and fuel oil pump. The cam shaft of course is a half time shaft, that is it makes one revolution while the main shaft is making two. The details of the valve gear can be seen from the cross section shown.

A good illustration of the use of this engine is shown in which a three cylinder engine is directly connected to a duplex outside packed pump.



The "Polar" Diesel Engine.

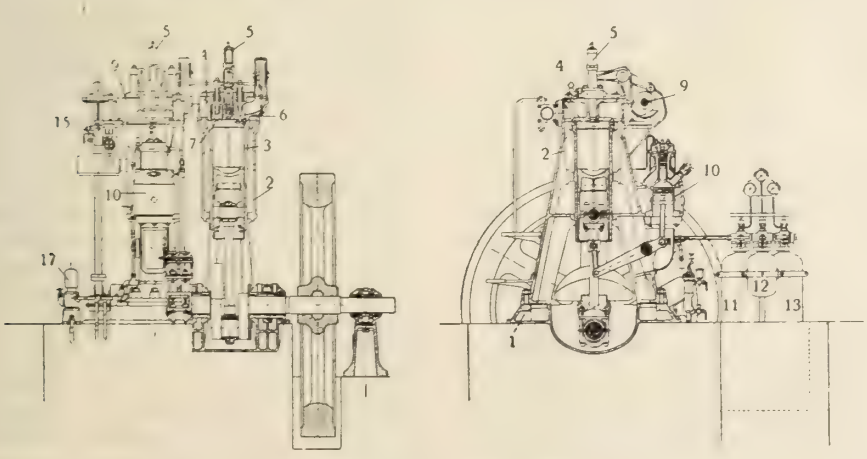
An European Type

A vertical four cycle Diesel engine made in Sweden by the Atlas Diesel Co., of Stockholm and handled in Canada by Lanmers & Maase, Montreal, is shown as affording an example of the design developed by European makers. The Diesel engine was adopted in Europe to a greater extent than in this country, both for marine and stationary purposes, and Sweden has always been a leader in this direction.

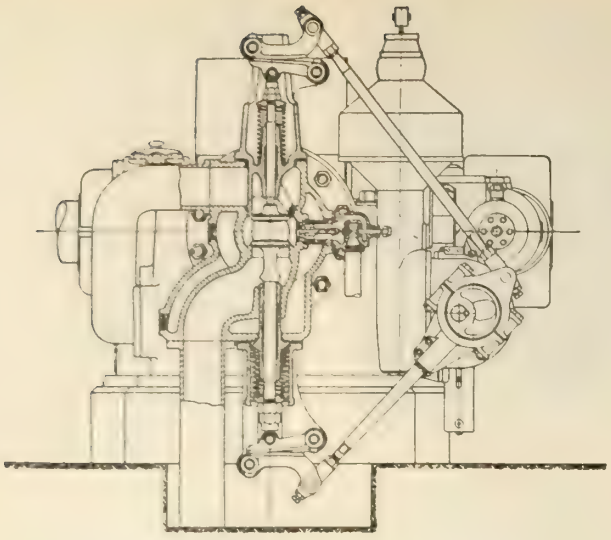
The principle of the engine is of course the same wherever it is built, and it is only in details that any difference can be noted. Thus it will be noticed that in the engine shown here, the air compressor is worked by means of a lever attached to the connecting rod of one cylinder, and is carried on the back of the engine, instead of at the end of the cylinders. The air compressor discharges into three different bottles, one of which is a spare receiver, the small one 12 being the injection air receiver while the third is the starting air receiver.

The cross section illustrated gives a good idea of the general arrangement, and the following description applies to the drawing.

On the bedplate (1) containing the main bearings are mounted columns (2) on which the cylinder liner (3) is fixed. The working cylinder is open at its lower end and closed at the upper end by the cover (4) containing the necessary valves. In each cylinder cover is one fuel valve (5) for the injection of the fuel, one air inlet valve (6), one exhaust valve (7) and also a starting valve for one cylinder on each engine. The valves are all controlled from the shaft (x). The air compressor built in tandem (10) produces the air necessary for starting and for injecting the fuel into the combustion chamber. The air is stored in the starting air receiver (11), the injection air receiver (12) and



Cross-section of "Polar" engine



Valve gear Allis-Chalmers engine

spare air receiver (13), the air compressor being of ample proportions f maintaining a sufficient supply.

The fuel oil is led in closed pipes (14) under low pressure to the fuel pump (15) which forces an amount of fuel corresponding to the load into the fuel valve (5). The fuel is then injected into the combustion chamber by means of air compressed to about 55—60 atm. from the above mentioned injection air receiver (12). The parts of the engine subjected to great heat, such as cylinder cover, cylinder, and air compressor, are water cooled, the water being obtained either from an ordinary outside pipe line (16) or through a water pump (17).

These three types give a good idea of the general construction of the Diesel engine for stationary purposes, that is as far as the full Diesel type is concerned. There are still the semi-Diesel and the gasoline engines to consider, and in the remaining articles we hope to cover some of these types, and also some detailed descriptions of plants where they are installed.

BRITISH AIR LIFT PRACTICE

At the latest meeting of the British Association, Dr. John S. Owens presented an interesting paper dealing with air lift pumping, his object being rather to call attention to the possibilities of the air lift than to indicate any final conclusions as to best design and application.

He had made some experiments with the object of producing the best pump for lifting acid mine liquors in the mine of San Domingos, in Portugal. The work that had been done convinced him that the low efficiencies usually obtained were not an essential part to get pump efficiencies with air lifts of between 60 and 70 per cent.

Causes of loss in air lift pumps could be grouped under the following heads: —(1) Slippage losses, due to relative motion between air bubbles and water; (2) losses due to friction of the mixture of air and water in the rising main; (3) friction losses incurred by the flow of water before air was admitted; (4) energy discharged in the kinetic form with the water and due to the velocity of discharge.

The losses under headings (3) and (4) were more or less under control. It was in connection with those under (1) and (2) that there appeared to be a good opportunity for increased economy.

Many experiments had been made already dealing with the question of submergence, and it had been definitely established that there was a most suitable value for this, the best efficiency being obtained with a submergence of about 70 per cent., that was when the length of submerged pipe was 70 per cent. of the total length—submergence + lift.

With regard to the loss arising from slippage, it was clear that a high velocity of the mixture tended to a slow slippage loss. The loss due to friction of the mixture in the eduction pipe was often considerable. It varied directly with the square of the velocity, while those from slippage varied inversely with the velocity, and the aim of the designer was to fix a definite value fof the velocity where the sum of the friction and slippage losses would be at a minimum. It was a well-established characteristic of air lift pumps that the highest efficiency was obtained at one particular delivery. The most suitable value for the submergence was best found experimentally, but seemed usually to be between 65 and 75 per cent. An appreciable effect was, however, to be obtained by very small variations in submergence. Taking v as the mean square of velocity in the pipe and f as the coefficient of friction, tests gave a value of f=0.025 in a 6⅝-in. pipe with v mean=13.3. The effect of nozzle diameter was found to be very slight, the governing factor being the rate of flow of air through the orifice. Describing the air lift mine pump, the author said that the installation was in two lifts—one of which raised the water from the 210 m. to the 180 m. floor, and the other raised the water to the 150 m. floor. It was found that the efficiency of the upper lift pump varied between 56.6 and 64.13 per cent., and that of the lower lift pump, from 52.5 to 66.1 per cent. The throat piece with the smallest diameter was found to give the highest efficiency—a result which was somewhat unexpected. The probable explanation was the effect on the size of bubbles. The smallest throat yet tried had a diameter of 3½ in., and this was being experimentally reduced to 2½ in. This installation had replaced a three-throw electrically driven ram pump which had been a constant source of trouble.

OTTAWA LODGE NO. 6, C.A.S.E.

A very interesting and instructive meeting was held by Ottawa Lodge on Wednesday evening, January 25, when Mr. T. A. Hatfield, of the Babcock & Wilcox Co., entertained the members to an excellent illustrated lecture on Babcock & Wilcox boilers. Mr. Hatfield gave some very useful information both as regards the early development of the boiler and the present day designs for burning either coal or oil and also especially designed furnaces for burning the various fuels used in different parts of the country.

A good attendance and great satisfaction were two of the good featur of the evening.

The Examinations of Grand Lodge Educational Committee are receiving their full share of discussion by our Lodge and good results are looked for.

A VALVELESS, GEARLESS ENGINE

Any user of internal combustion engines will need no strong argument for the advantage of doing away, if possible, with valves and gears, both of which are a fruitful source of operating difficulties. The idea of an engine without valves or gear has been realised in Great Britain by the construction of an engine which, in the works at least, has given remarkably promising results. This engine has three cylinders; and except for the ports it has no valves. There is not a single gear wheel and all the usual cams, shafts, tappets and springs —even the timing gear—are cut out. The only moving parts are the crank shafts, pistons and connecting rods. The experimental engine was rated at ten horse power and on test developed twice as much. The cycle of operations is not easily described without a detailed diagram but it must be said to depend upon ingenious inter-working between the three cylinders. This engine has been specially designed to meet the conditions in overseas countries, where an extremely simple engine not requiring difficult repairs is for obvious reasons in great demand.

Packing a Rod For 500,000 Lbs. Pressure

The Necessity for Packing Against Pressures Running From 300,000 lbs. to 500,000 lbs. per Sq. Inch Arose During the Making of Some Laboratory Experiments. The Methods Adopted Should Interest The Power Engineer

By P. W. BRIDGMAN.

I RECENTLY described some experiments at Harvard University with extremely high pressures. These pressures were of the order of 300,000 lbs. per square inch or ten times the firing pressure of a gun. One absolute essential in handling such pressures is a suitable method of packing the joints, says Mr. P. W. Bridgman in the "Compressed Air Magazine."

Since this question has aroused some inquiries, and since the principle of the packing is applicable to any pressure, I shall describe the packing in principle and some of the details of its application. I shall also describe some results of engineering interest obtained from the high pressure experiments which were only briefly alluded to in the former article.

The principle of the packing will be obvious from a study of Figs. 1, 2 and 3, which illustrate three stages in the evolution of the packing. In Fig. 1 is shown the ordinary method of packing a joint applied to an air pipe connected to a large vessel. Such a packing is familiar to anyone who has pumped an automobile tire. The packing material is squeezed between two opposing members with sufficient force to prevent the air or water, or whatever is carried by the pipe from leaking. The weakness of this packing is at once evident. The packing material squeezes out between the opposing members if screwed up too tightly, so that the joint has to be continually retightened, until eventually all the packing material escapes. The pressures that this packing can handle are moderate, the limit is set by the pressure that blows out the packing.

A modification of this arrangemen by putting a retaining rim around the outer edge of the packing as shown in Fig. 2, prevents the packing from squeezing sideways, and greatly increases the pressure that it is possible to pack against, because the packing itself may be subjected to a much greater pressure without lateral escape. It is still better if the opposing members are brought into contact with a direct straight push instead of by the rotary motion as in the figure, which has danger of abrading the surface of the packing by the twisting motion.

This simple practice of enclosing the packing on all sides is easy enough when pointed out, but the possibilities of it in scientific work were first realized by the French physicist, Amagat, who by the consistent use of it was able to extend by a range of six-fold the pressures which were accessible to science.

There is an essential limitation to the

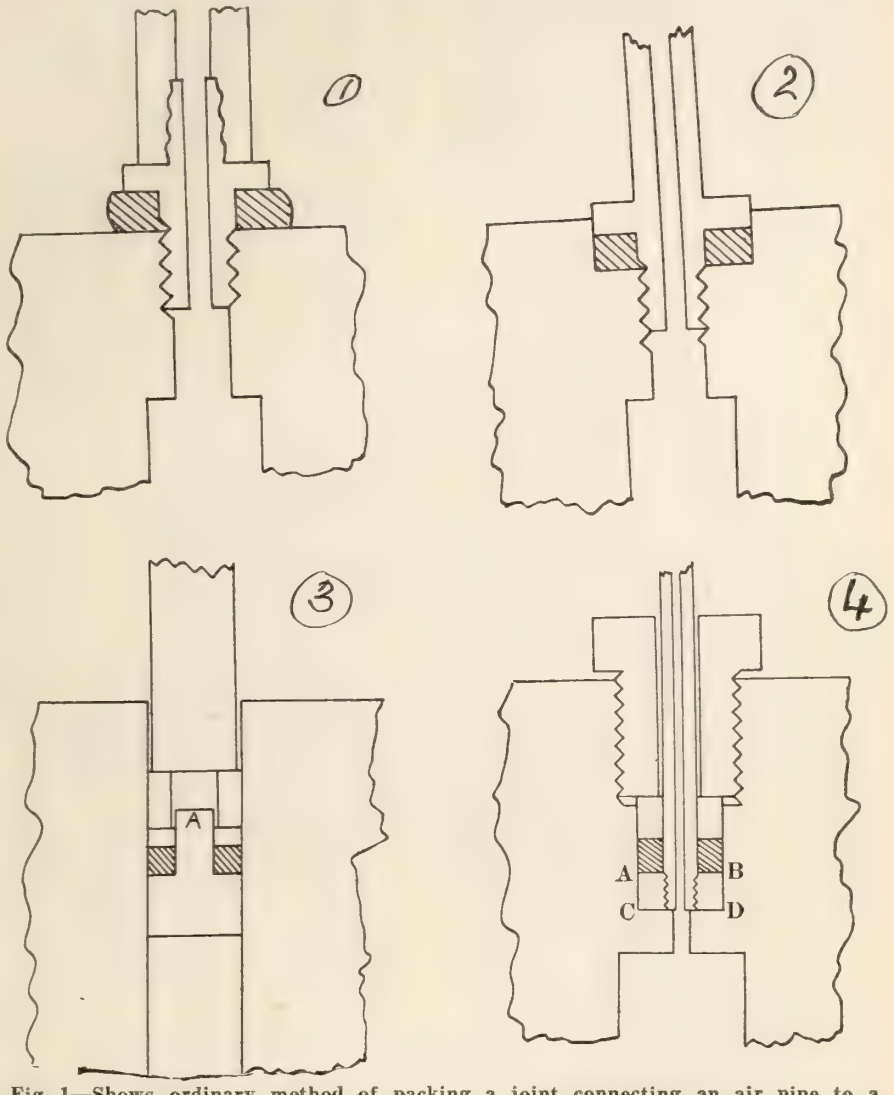


Fig. 1—Shows ordinary method of packing a joint connecting an air pipe to a large vessel.

Fig. 2—Shows a retaining rim around the outer edge of the packing.

Fig. 3—Shows packing on back side of the washer.

Fig. 4—Pressures up to nearly 500,000 lbs. per sq. in. have been obtained with this packing.

pressures that can be maintained by a packing like that of Fig. 2. If at any time the pressure in the liquid rises as high as the pressure in the packing, the packing loses its tight pressure against the walls which retain it, and the liquid leaks past. If for instance, it is desired to pack against a pressure of 200,000 lbs. per sq. in., the screw by which the packing is tightened must be forced tight enough to give an initial pressure in the packing of at least 200,000 lbs. per sq. in. The simplest modification of the packing of Fig. 2 will change all this. Let us put the packing on the back side instead of the front side of the washer at the end of the pipe, as in Fig. 3. We now have a packing that cannot be made to leak by any pressure that the walls of the containing vessels themselves will stand. The application of a little high school mechanics will show the principle underlying the operation. What is it that prevents the pipe from blowing out of the hole? Obviously the pressure exerted by the packing on the ring AB. And what is it that tries to blow the pipe out of the hole? Obviously the pressure exerted by the liquid or gas on the end of the pipe CD. Now, since the pipe neither blows in or blows out, it is obvious that the total force trying to blow it out is equal to the total force holding

it in, or in other words, the total pressure exerted by the liquid over the area CD is equal to the total force exerted by the packing over the area AB. But the area AB is less than the area CD, hence the pressure in pounds per square inch in the packing is greater than the pressure in pounds per square inch in the liquid. The ratio by which the pressure in the packing is greater than the pressure in the liquid is the same as the ratio by which GD is greater than AB.

For example, if the diameter of the pipe is half the diameter of the hole, the area of AB is 3-4 of the area of CD, and the pressure in the packing is 33 per cent. greater than the pressure in the liquid. This excess pressure in the packing is maintained automatically no matter what the pressure in the liquid. If the pressure in the liquid is 1500 pounds per square inch, the excess pressure in the packing is 500 pounds, and if the pressure in the liquid is 150,000 pounds, the excess pressure in the packing is 50,000 pounds. Hence the liquid can never leak no matter how high the pressure, and the only limitation on the pressures that can be carried is imposed by the strength of the containing vessel. The only problem that now remains is the problem of preventing the packing itself from leaking. It is comparatively easy to do this by making the metal washers an accurate fit for the containing vessel, although there are complications at extremely high pressures. It is somewhat paradoxical that if the lower washer is not a tight enough fit, the packing will leak into the containing vessel instead of out, driven by its excess pressure against the pressure in the liquid. It is also somewhat paradoxical that under excessive pressures lead will leak through a smaller hole than rubber. The reason is that rubber becomes rigid, or more properly freezes under pressure, just as a rubber ball loses its elasticity when plunged in liquid air, but the lead is not greatly changed in its properties by the pressure.

The fundamental principle of this packing is that of the unsupported area, in virtue of which the pressure in the packing is always a fixed percentage higher than the pressure in the liquid. In the case illustrated in Fig. 3 the unsupported area is that of the pipe which projects beyond the restraining plug. In Fig. 4 another method of applying this packing idea is shown, this time to the packing for the end of a piston. Here the unsupported area is that of the end of the stem A. With this method of packing the piston, I have reached pressures in liquids up to nearly 500,000 lb. per sq. in. There is furthermore, absolute freedom from leak, so that except for the wearing of the piston the piston returns exactly to its original position after making a stroke. This permits numerous interesting applications in the way of making physical measurements at high pressures.

As illustrating the vagaries of the patent business it is interesting that I failed to get a fundamental patent on this idea because the plunger of a sausage machine had once shown a packing of this character, quite by accident, the peculiar design being for another purpose.

The principle of the unsupported area is capable of the most varied application. Anything may be used as a packing material that is sufficiently soft and flexible. The pressures are so tremendous that even soft steel flows into cracks left unguarded, and in some of my packing designs soft steel rings take the place of soft rubber and function with entire success.

Turning now from the question of the packing, I have observed a number of cases of rupture in dealing with these high pressures which are different from the sorts of rupture usually met with, and which are most instructive. It is strange that apparently the engineer has never determined precisely what it is that makes a material break. He can predict that a rod of steel will break if it is pulled too hard or twisted too much, but quite often he cannot tell in more complicated cases just when a substance will break or in other words, the conditions of rupture are known only for certain special simple cases. The discovery of unusual kinds of rupture is valuable in giving an idea of what may be the conditions of rupture in the general case.

One of the most surprising of these unusual cases may occur to the pipe of Fig. 3. If the pressure in the liquid rises too high, or even if the man with the monkey wrench who tightens the nut is too strong, the soft packing material will be squeezed bodily into the metal of the pipe, which will be pinched off and escape by blowing out through the screw plug. If the pressure at which this occurs is high, the ejection is with great violence, and is one of the chief sources of danger in these experiments with extremely high pressures. I have had plugs blown through eight or ten inches of wood in this way. Such a plug is seen in the first illustration. At the point A the solid steel rod was pinched off by the soft rubber packing. Fortunately the effect does not take place until the pressure in the packing has risen to something about as high as the tensile strength of the steel. Thus a mild steel pipe with a tensile strength of 50,000 lbs. per sq. in. will not fail in this way if the packing is properly designed until the pressure in the liquid has risen to about 50,000 pounds.

The significant thing in this "pinching-off" effect from the point of view of the theory of rupture is that there is no stress pulling apart the fibers that separate. The reason is that the end of the pipe is unsupported, so that there is no force along the length of the pipe. Rupture occurs because the increase of length of the longitudinal fibres of the pipe has become too great. It is exactly like squeezing off a string of putty in the hand. This single example is sufficient to show that it cannot be the force tending to rupture the fibres that is responsible for the break down of material. What then is responsible? It is perhaps the elongation of the fibres? No, it is not this, as we may show by another example, picked from the numerous kinds of ruptures that occur under high pressures. If we make a hard rubber ring with a steel core an exact fit for it, and put the ring with its core into a vessel with liquid, and subject the liquid to a great pressure, we find that the rubber ring is cracked exactly as it would be if it were stretched too much.

Now here is a paradox in more than one respect, for not only is the rubber ring prevented from shrinking by the steel core, so that rupture takes place across fibres in which there is no change of length (or at most a very small decrease of length), but the force in the fibres which rupture, is actually a compression instead of a tension, so that here rupture takes place against the direction of the force. What is then the true answer? It has not yet been worked out, and no one can as yet say exactly what it is that makes a piece of steel break, but curious examples such as these at least show that previous ideas have been wrong and ought to be of much value in suggesting what the correct answer is.

There are other paradoxical effects to be found in the way in which materials rupture under high pressures. Suppose for example that a thick hollow steel cylinder is exposed to pressure over the outside surface in such a way as to tend to collapse it. If the tube is not too thick, it will collapse when the pressure becomes too high by folding in on itself in one or more folds, as a boiler tube sometimes fails. But if the tube has more than a critical thickness, it cannot fail in this way by folding, but must yield differently.

In fact it flows toward the center, so that if the pressure is pushed high enough, we finally squeeze the internal hole out of existence, and have left a cylinder to all apearances that is solid. This will take place at about the same pressure, no matter how thick the cylinder is, which again is paradoxical. If the cylinder is made of soft steel, the hole will be squeezed out of a cylinder with even infinitely thick walls by a pressure of 250,000 pounds per sq. in. Suppose now that instead of trying to collapse a steel tube, we try the same experiment with one of glass. One would be tempted to say that of course the glass tube could not stand as much pressure as the steel one. This is true of a thin cylinder, for a thin glass tube will break into a thousand fragments at a much lower pressure than a steel tube would support.

But if the tube is thicker, there is a complete reversal of behavior and a thick tube of glass will support a very much greater pressure on the outside than will one of steel.

I have subjected hollow cylinders of glass to pressure of 350,000 lbs. per sq. in., without producing any appreciable effect. Yet if a piece of glass is subjected to an ordinary crushing test in a testing machine, it will break at not more than 15,000 or 20,000 lbs. per sq. in.

The essential difference between steel and glass seems to be that the steel is composed of microscopic crystals which can flow under pressure, whereas there are no crystals to flow in the glass, which therefore has no way of yielding, and therefore cannot help but support the pressure. One can see of how much interest these matters are for the geologist, who wants to know whether there are open cavities in the interior of the earth.

I have made similar experiments on various minerals in order to find how these substances may behave in the interior of the earth. Hollow crystals of materials such as quartz will stand a much greater stress without collapse when this stress is a pressure such as that exerted in a testing machine. The figures obtained by the ordinary tests for the strength of the minerals of which the surface of the earth is composed are much too low, and false conclusions are drawn. When a hollow cylinder, such as quartz, does break under very heavy pressure on the outside, the break is of an unusual character. The inside surface disintegrates and flies off into fragments as fine as dust.

These fragments are projected from the interior surface with almost explosive violence, so that if a rod of metal is placed inside the cavity, its surface will be frosted by minute slivers of rock that have been shot into it like bullets. The disintegration of the rock continues until the hole is so tightly packed with debris as to exert sufficient pressure on the interior walls to counterbalance the effect of the external pressure.

Now it is another curious fact that it is never possible to pack the debris so closely that it has the density of the rock from which it came. I have made experiments on rocks up to pressures of 500,000 lb. per sq. in., and have never been able to force the pieces back into their original volume.

This means that minute fissures persist between the fragments of comminuted rock at very great depths, and that it is possible that water or gas may circulate between the fragments and produce important geological effects.

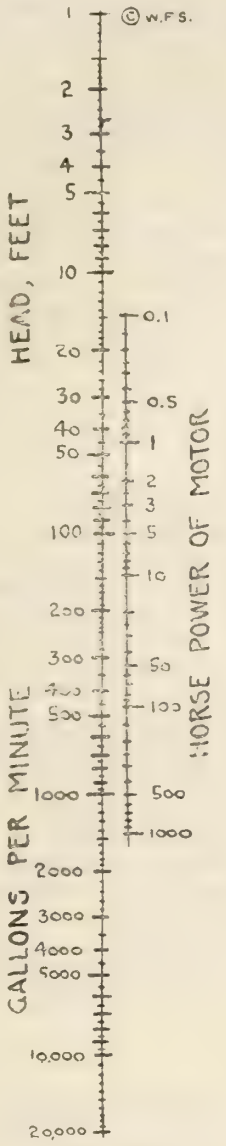
The Pittsburgh, Pa., Experimental Station of the Bureau of Mines is continuing laboratory experiments on coal ash fusibility, oxidizing and reducing atmospheres by the micropyrometer method, and comparing the results with those of the gas furnace. By using a reducing atmosphere in the micropyrometer furnace, fairly good checks were obtained on ash, the average in the micropyrometer method being about 150 degrees F. lower. While the micropyrometer method cannot be used as an alternate method if close checks are required, it can no doubt be used as a rapid method for determining the fusibility of coal ash. The results of this investigation are now being tabulated.

A new investigation, to determine the composition of the gas arising from a fuel bed, is under way at the Pittsburgh Experimental Station.

MOTOR OR ENGINE SIZES FOR PUMPING WATER

By W. F. Schaphorst

This little chart will be found handy for determining the power or size of electric motor to install for pumping. How many gallons do you want to pump



Pump Chart.

per minute? How high or against what head will you pump. This chart gives the answer in a very simple way. It gives the answer under "average" conditions taking into consideration the pump efficiency, friction of water in piping, etc.

For example, what size of motor will it take to pump 2,000 gallons of water per minute against a head of 10 feet?

Find the point midway between the 10 and 2,000 in column A. Opposite that point you will find the answer—9 horse power.

To find the mid-point there are many quick and simple ways. Use a pair of dividers, a ruler, fold a piece of paper, etc.

BOOK REVIEW

We have received from the D. Van Norstrand Company, New York, a copy of "Testing of Electrical Machinery," written by J. H. Morecroft, E.E.B.S., Associate Professor of Electrical Engineering, Columbia University. The book is intended as a short course in the subject of its title for non-electrical students, and is a specially valuable contribution to the literature on this subject, as far as the power plant engineer is concerned. The book is written as a description of a series of experiments beginning with the determining of the fall of potential in a conductor carrying electrical current, the testing of efficiency of various kinds of direct and alternating electrical machinery, the tracing of faults in machines and wiring. It also includes chapters on illumination, and the use and principles of storage batteries. It is a useful book to be in the office of any chief engineer, and is well illustrated by diagrams of the various tests and experiments carried out. There are a set of questions at the end of each chapter.

CATALOGUE

The Pelton Water Wheel Co., of San Francisco and New York, has issued Bulletin No. 17 "Pelton Water Wheels (Impulse Turbines) and Reaction Turbines." The bulletin describes the various types of hydraulic equipment manufactured by the company, and discusses their application both to the generation of hydro-electric power and to the direct operation of many different kinds of machinery. Some space is also devoted to governors and to pressure regulating devices. The bulletin comprises 48 pages and is illustrated by a number of drawings and photographs. Copies may be obtained upon application to either office of the company.

We have received bulletins Nos. 220 and 221 from the Uehling Instrument Co., Paterson, N. J. The first deals with the magnitude of the losses due to the chimney in a power plant, and contains diagrams reproduced from a paper issued by the U. S. Department of Mines. The bulletin No. 221 deals with the relation between CO_2 and the money wasted up the chimney and contains tables of these losses with different kinds of fuels. A set of curves showing the saving by increasing the percentage of CO_2 in the flue gases is also given.

The Bird Archer Co., 90 West Street, New York, have issued a bulletin describing their "Baco" wash out plug, and locomotive type blow off cocks. The latter is fully described and illustrated.

Wallace & Tiernan have issued a bulletin describing their chlorination process as applied to drinking water, which is made in sizes suitable for municipalities or individual plants. The bulletin is entitled "Is Your Own Town on the Map," and gives a map showing the location of their installations in the U. S. and Canada.

A. S. M. E. Code for Compressors and Blowers

The Preliminary Draft of the Test Code for Testing Air and Ammonia Compressors, of Reciprocating and Centrifugal Type, Including Air and Vacuum Pumps, by the Committee on Power List Codes

IN 1918 the Power Test Committee of the A. S. M. E. was reorganized to revise and enlarge the Power Test Codes of the Society, published in 1915. The Committee is a large one, consisting of a Main Committee of 25 under the chairmanship of Fred R. Low, and 19 Individual Committees of specialists who are drafting codes for the different classes of apparatus comprised in power-plant equipment. Below is reproduced the fifth of these codes to be completed, namely, the Test Code for Displacement Compressors and Blowers.

The Individual Committee which developed this Code is headed by Mr. Paul Diserens as Chairman, and consists of the following men: Hugh V. Conrad, John F. G. Miller, Snowden B. Redfield, Carl G. Sprado, Charles Prentice Turner, and John T. Wilkin. This Committee will welcome suggestions for corrections or additions to this draft of its Code and especially desires constructive comment on Par. 10 and 10a. These should be addressed to the Chairman, care of The American Society of Mechanical Engineers.

Introduction

1. The code for displacement compressors and blowers is intended as a guide for testing reciprocating piston compressors and blowers, as well as rotary compressors and blowers of the positive displacement type. The tables for data and results apply to complete units including compressor element and driving element, but the code itself constitutes a set of rules for the test of the compressor element only. For the driving element the codes for steam engines, steam turbines, internal-combustion engines, water wheels, etc., depending upon the method of drive, should be consulted and followed.

Object

2 In accordance with the "General Instructions," the object of the test should be determined and recorded. If the object relates to the fulfillment of a contract guarantee, an agreement should be made between the interested parties concerning all matters about which dispute may arise, as noted in Par. 2 of the "General Instructions," and the points agreed upon should be stated in the report of the test.

Measurements

3 The measurements to be made in any test of a compressor or blower have for their purpose the determination of the following essential quantities:

(a) The quantity of air or gas compressed and delivered expressed in cubic feet in terms of gas or air under intake conditions of temperature and pressure

(b) The average intake and discharge pressures

(c) The power required to compress and deliver the measured amount of air or gas handled

(d) The amount of steam, electrical energy or fuel, depending upon the method of drive, consumed by the driving element during the test.

In order to arrive at these quantities and as a means of interpreting them, the following measurements are necessary:

(e) Diameter and stroke of compressor cylinders, or equivalent dimensions for positive rotary blower.

(f) Diameter of piston rods

(g) Number and dimensions of intercoolers and aftercoolers

(h) Principal dimensions of driving element (See appropriate code)

(i) Speed in r. p. m. and total number of revolutions

(j) Indicated horsepower in compressor and driving cylinders (steam engine, internal-combustion engine, etc.)

(k) Discharge pressure

(l) Intake pressure

(m) Intercooler pressure

(n) Barometric pressure

(o) Temperature of air or gas before and after each stage

(p) Temperature of cooling water at inlet and outlet of each jacket and cooler

(q) Quantity of jacket and cooling water

(r) Temperatures, pressures, etc., steam, gas or oil as applied to driving element (See appropriate code).

Instruments and Apparatus

4 The instruments and apparatus necessary for the measurement of the quantities enumerated in Par. 3 are:

(a) Gaging tank and nozzle or orifice for measuring air or gas compressed

(b) Tanks and platform scales of suitable capacity for measuring the quantity of condensed steam when a steam engine constitutes the driving element or for measuring fuel oil when an oil engine constitutes the driving element.

(c) Water meters or calibrated tanks, or tanks and platform scales for measuring jacket and intercooler circulating water

(d) Pressure gages, vacuum gages, water and mercury manometers, and thermometers

(e) Barometer

(f) Steam calorimeter (for steam-engine-driven compressor)

(g) Voltmeter, ammeter, wattmeter and power-factor meter for measuring electrical input for motor-driven compressors

(h) Revolution counter

(i) Indicators

(j) A planimeter

(k) A deadweight gage tester

Directions for the use and calibration of instruments and apparatus enumerated above are given in Pars. Nos.—of the code on "Instruments and Apparatus."

4a The measurement of the quantity of air compressed shall be by the following method:

(a) In the case of a compressor or blower: Flow into the atmosphere through nozzle or orifice from a gaging tank on the discharge side of the compressor or blower

(b) In the case of a vacuum pump: Flow from atmosphere through a nozzle or orifice into a gaging tank on the intake side of the vacuum pump.

4b Where the foregoing prescribed method is impracticable, as for example in the case of a compressor handling inflammable gas or gas which cannot be wasted, one of the following instruments may be used. These alternatives are listed in order of preference.

(c) Venturi meter

(d) Nozzle or orifice in discharge line

(e) Receiver tanks of known capacity into which the discharge from the compressor may be delivered, to be used only for compressors working at a discharge pressure of 1000 lb. per sq. in. or greater.

If method (c) or (d) is used, the instrument should be applied in a pipe through which the gas is permitted to flow under a pressure considerably less than the compressor discharge pressure. The reduction in pressure can be brought about by throttling and will result in eliminating, or at least minimizing, the pulsations in flow induced by the compressor.

4c The kind and size of gaging tank and nozzle or orifice selected will depend upon the particular method chosen for measuring the quantity of air or gas compressed. Whenever possible a low-pressure nozzle or orifice shall be used. A low-pressure nozzle is one through which the drop in pressure is small, that is, one in which the upstream absolute pressure is less than twice the downstream absolute pressure. Its use for high or moderate-pressure compressors

Mr. Read approves the draft of the Code as presented with the exception of Par. 10a. He believes that the amount of moisture removed from the separator should be weighed and that this weight should enter into the calculations.

involves throttling the gas before it is admitted into the gaging tank to such an extent that all, or nearly all, pulsation is eliminated. If a high-pressure nozzle is selected, that is, one through which the drop in pressure is relatively large (P_1—$2P_2$), care should be exercised to select an orifice of a size sufficient to insure as much throttling between discharge receiver and the gaging tank as possible.

4d The measurement of the intake and discharge pressures shall be by gage attached at the desired point, the fluctuations of which are reduced as far as may be by choking the gage cock. When extreme accuracy is desired or when the fluctuations are large, the average pressure may be found by working up pipe diagrams taken at or near the same point, thereby determining the mean pressure for the entire stroke.

Preparation

5 Before proceeding with a test of a compressor or blower, Pars. 4 to 8 of the "General Instructions" should be carefully read. The dimensions and physical conditions not only of the compressor but of all the associated parts of the plant essential to the object of the tests should be determined and carefully recorded.

5a Dimensions. The dimensions of the compressor cylinders should be determined by actually measuring the machine itself without reference to the drawings. If the cylinders are much worn the average diameter should be taken, but proper record of the fact should be noted.

5b The method for measuring clearance will depend upon the particular design of the compressor in question. In a reciprocating displacement compressor with valves of the automatic type, the mist satisfactory method will be to calculate the clearance from the measured dimensions of the cylinder, its several ports, and passages. If detailed drawings are available it will be found convenient to check each dimension of the parts involved by actual measurement and from this information compute the clearance volume. If mechanically operated valves are used, or if the construction of the valves of the automatic type is such as to permit blocking them in their closed position, the clearance may be obtained by the water-measurement method. This should only be attempted, however, when extreme accuracy is necessary or desirable. To carry out this method, refer to Par. 5a of the Code for Steam Engines.

5c The area of the compressor cylinder-jacket surface is that part of the cylinder wall or cylinder-head wall in contact with the water circulation and should be measured on the dry side of the metal.

5d The intercooler and aftercooler surface should be measured on the dry side of the cooling surface. Surface in contact with the air to be cooled on the one side and the atmospheric air on the other side should not be included as cooling surface. If a record of its amount is made it should be listed as a separate item.

Operating Conditions

6 As pointed out in the "General Instructions," Par. 19, in all tests in which the object is to determine the performance under conditions of maximum efficiency, or where it is desired to ascertain the effect of predetermined conditions of operation, all such conditions which have an appreciable effect upon the efficiency should be maintained as nearly uniform during the trial as the limitations of practical work will permit.

Tests to determine the performance under working conditions in which no attempt at uniformity is made are not advised, since the only available method of air measurement involves the determination of the rate of flow and total quantities of gas or air must be computed from the observed rate. Unless all conditions of operation are kept uniform or nearly uniform, the results obtained will not be of any value.

Starting and Stopping

7 The compressor should be operated under test conditions for a considerable period before a record of its performance is made. This period should be of a duration sufficient to bring about a steady condition of pressure, temperature and speed. In this connection Pars. 16 and 18 of the "General Instructions" should be carefully noted.

Duration

8 The duration of compressor tests will generally be governed by the requirements insofar as the driving element is concerned, and for direction as to the necessary period reference to the appropriate code governing the driving element should be made. In the case of a motor-driven unit accurate results can be obtained from very short tests, the controlling factor being the time required to record enough sets of observations to demonstrate the uniformity of running conditions during the test.

Record

9 The general data should be recorded as pointed out in Pars. 20 to 30 of the "General Instructions." Instruments should be read and indicator cards taken from each end of each cylinder at least quarter-hourly when the conditions are uniform, and oftener when there is much variation. For short tests referred to in Par. 8, readings and cards should be taken much more often. If there are wide fluctuations in readings they should be shown by recording instruments. Each indicator card should be marked with the number, date, time, scale of spring, and end of cylinder, and on one card of each set the readings of the pressure gages should be recorded. The log should contain the record of the readings of discharge, intercooler and intake gages, thermometers, revolution counter, speed indicator, gaging-tank pressures and temperatures, and all other instruments, and these readings should be obtained at practically the same time the indicator cards are taken. The areas, length and mean effective pressures shown by the indicator cards should also be entered in the log. If complete test data are required, representative pipe diagrams should be taken with an indicator applied near the cylinder port and operated by connection to a reducing motion driven from the engine or the compressor cross head.

9a A set of specimen indicator diagrams should be carefully selected from the whole number taken, and these should be embodied in the record. The specimen cards selected should be such as to show the average conditions of pressure. If pipe or port diagrams are obtained, specimens of these should also be placed in the record.

Calculation of Results

10 Volume of Air or Gas Compressed. The measurement of the amount of air or gas through a nozzle, orifice, or venturi tube results in a determination expressed in pounds per unit of time. (See Code for Instruments and Apparatus, Par.—.) The results obtained must therefore be reduced to terms of volume at the temperature and pressure obtaining at the compressor or blower intake. For this purpose the required specific weight at intake conditions may be calculated from the following formula:

$$\text{Specific Weight} = \frac{P \times 144}{RT} \text{ in lb. per cu. ft.}$$

where P = absolute intake pressure, lb. per sq. in.

T = absolute intake temperature, deg. Fahr.

R = constant (=53.3 for air)

This assumes that the fluid compressed is ideal gas, an assumption quite satisfactory for air. The weight of air or gas per minute as shown by nozzle measurement divided by the specific weight at intake conditions is equal to the volume of free gas or air compresser per minute.

When natural gas is compressed the value R is not nearly enough constant under all conditions to satisfy engineering requirements and a correction must be made, depending in amount on the ratio of compression and the nature of the gas. (See Code for Instruments and Apparatus, Par.—.)

10a[1] Correction for Moisture. In the case of a compressor handling moist air, if some of the moisture is condensed during the process of intercooling and aftercooling, the air under discharge pressure will be saturated. In order to correct the rate of flow as shown by the orifice results it will only be necessary to figure the capacity of the compressor in terms of a total pressure equal to the sum of the partial pressure of air under intake conditions plus the partial pressure of the moisture in moist air having a relative humidity less than that observed in the intake by an amount representing the moisture removed in the cylinders, intercoolers, and aftercoolers. To determine this equivalent pressure to be used in calculating the specific

volume, the following formula may be used:

$$P = P^d + P^m$$

where P^d = partial pressure for air in intake

P^m = partial pressure of moisture corrected for water of condensation and removed from compressor and coolers.

To arrive at the value for P^m, proceed as follows: In the steam tables find the density of steam corresponding to the receiver. Multiply this first by the ratio of the observed absolute intake pressure to the observed absolute discharge pressure and then by the ratio of the absolute temperature in the discharge receiver to the absolute temperature in the intake. The value thus obtained will be a hypothetical density, opposite which in the pressure column of the steam table will be found the desired partial pressure P^m.

It should be noted that the correction for moisture may be properly made only if moisture in the form of condensate is actually removed from the coolers. Care should be taken to make sure that the discharge temperature and pressure used is taken at or near the outlet of the cooler. If no aftercooler is installed the discharge temperature and pressure at or near the outlet of the intercooler should be used in the calculation outlined above.

11 Indicated Horsepower. The indicated horsepower for each end of the cylinder is found by using the formula:

$$\text{I. hp.} = \frac{PLAN}{33{,}000}$$

where P represents the mean effective pressure in pounds per square inch, L the length of the stroke in feet, A the area in square inches of the piston less the area of the piston rod, if any, and N the number of revolutions per minute. The total horsepower of the cylinder is the sum of the horsepower developed in the two ends.

11a The Mean Effective Pressure should be found by dividing the area of the indicator diagram in square inches as determined with a planimeter by the length of the diagram in inches, and multiplying the quotient by the average scale of the indicator spring. If a planimeter is not available, the approximate mean effective pressure may be determined by finding the average height of the diagram in inches as obtained by averaging a suitable number of ordinates, at least twenty, measured between the lines of the forward and return strokes, and then multiplying this average by the scale of the spring. The length of the indicator diagram is the measured distance along the atmospheric-pressure line between ordinates erected perpendicular to it and passing through the ends of the indicator diagram.

12 The horsepower required to compress isothermally the measured quantity of air at average speed on the compressor is found by multiplying the volume compressed per minute in cubic feet corrected to intake pressure and temperature by absolute intake pressure in pounds per square foot and by the hyperbolic logarithm of the ratio of the absolute discharge pressure to the absolute intake pressure and dividing the product by 33,000.

13 The Gross Horsepower is the indicated horsepower in the steam or power cylinders in the case of a steam or internal-combustion-engine-driven compressor; the electrical horsepower multiplied by the motor efficiency in the case of a motor-driven compressor; and the brake horsepower delivered to the compressor shaft in the case of a belt-driven compressor. In the case of a compressor driven through belt, gear, etc., the power absorbed by the belt, gear, etc., must be taken into account.

14 Electrical Horsepower. The electrical horsepower of a motor is found by dividing the input at the terminals expressed in kilowatts by the constant 0.746. In the case of an alternating-current motor, the input determined, whether expressed in electrical horsepower or kilowatts, should be the total input. When the power for excitation or ventilation is taken directly from the compressor shaft, the total input is that indicated at the a. c. motor terminals; but if the motor efficiency as given does not account for the exciter input and exciter loss, the total electrical horsepower (Par. 13) is that indicated at the motor terminals less an equivalent current required to run the exciter.

15 Volumetric Efficiency. The volumetric efficiency is the ratio of the capacity of the compressor to displacement. The capacity is the actual amount of air or gas compressed and delivered, expressed in cubic feet per minute at intake temperature and pressure.

16 Mechanical Efficiency. The mechanical efficiency is the ratio of the air indicated horsepower to the indicated horsepower in the power cylinders in the case of a steam-driven or internal-combustion-engine-driven compressor, and to the brake horsepower delivered to the shaft in the case of a power-driven machine.

17 Compression Efficiency. The compression efficiency is the ratio of the work required to compress isothermally all the air or gas delivered by the compressor to the work done within the compressor cylinder, as shown by the indicator cards. The two factors involved in this ratio are defined in Pars. 12 and 11, respectively.

18 Overall Efficiency. The overall efficiency is the product of the compression efficiency and the mechanical efficiency.

The Data and Results

19 The data and results should be reported in accordance with the tables given herewith, adding lines for data not provided for or omitting those not required, as may conform to the purposes of the test. Unless otherwise indicated, the items should be the averages of all observations.

Table 1 constitutes the data and results applying to the compressing element and Tables 2, 3 and 4 the data and results applying to the driving element for motor, steam-engine and internal-combustion-engine drive, respectively. In reporting a test Table 1 should be combined with its appropriate driving-element table, the two being thrown together to form one complete table. The items of Tables 1, 2, 3 and 4 are so numbered as to indicate how this may be done most conveniently.

Table 4—Additional Items Applying Only When the Driving Element is an Internal-Combustion Engine.

(The items of this table will be developed upon the completion of the Test Code for Internal-Combustion Engines).

BRITISH CONCRETE MACHINERY

At a recent exhibition held in London, a remarkable display of concrete machinery of various kinds was made by a large number of British firms. One of these machines was a concrete block maker capable of turning out 1,000 blocks in an 8-hours' working day, or 130 partition slabs per hour. When used on a house building contract two of these machines turned out on the average of 2,400 blocks per day of 8 hours for a period of two months. On one day the two machines actually produced 3,320 blocks in 8 hours. Another machine designed for making concrete slabs for paving purposes averaged between 40 and 50 slabs in the hour, and has produced as many as 60 per hour under service conditions. A third machine is capable of producing everything in the way of material that a builder or anyone undertaking repairs to property may require. Blocks of various sizes, bricks, window-sills, steps, hearths, mantlepieces, wall-coursing, and so on, can all be produced by this machine.

We have received from Darling Brothers, Ltd., Montreal and Toronto, a bulletin describing the Young Centrifugal Vacuum and Boiler Feed Outfit, which has been designed for operating vacuum heating systems. The apparatus consists of a self-contained unit mounted on a bed plate, which carries the receiving tank, the centrifugal pump, and the motor for driving. Operation is entirely automatic, being controlled from a float in the tank. Vacuum of from 4 to 10 inches is maintained on the system it is claimed by this device.

In the study of the ignition of coal dust clouds in open air, being conducted at the Experimental Mine of the Bureau of Mines, Bruceton, Pa., tests were recently made with pulverized Pittsburgh coal and with pulverized Colorado lignite. In some of these tests flame extended 45 feet into clouds that were 50 feet long, the lignite dust cloud making a larger flame than Pittsburgh coal dust. An attempt will be made to get a greater length of flame with an increased length of dust cloud.

At the central district station of the Bureau of Mines, Urbana, Ill., a study has been made of the inhibiting effect of finely divided fusain or mother coal on the coking property of Illinois coal. Coking tests were made on coal containing up to 10 per cent. 200-mesh mother coal without making any appreciable deleterious influence.

The Field of Opportunity

A CONTRIBUTOR in this issue draws attention to the possibilities open to the engineer of the present day for the display of individual power and initiation in the power plant, of the modern type. He includes the small, medium, and large plants in his outlook, and gives instances of differences in cost of operation in a number of pulp and paper mills.

While we agree perfectly with him we do not think he goes far enough when he confines the opportunities to the engineer in the modern plant. Frequently the engineer in the more old-fashioned and less efficient plant has better opportunities to make a showing for himself and a saving for the owner than is the case in the highly modernized establishment.

The engineer in the latter plant has usually a high standard to work to, and if he succeeds in keeping up to the standard, that is about as much as he can hope to do, whereas his colleague in the plant where efficiency is only a quality that has been heard of academically, has an immense field for immediate improvement open to him. This is, perhaps, an old theme, but it is one that can bear propagating unceasingly, especially in this country, where the modern efficient plant is still somewhat of a curiosity, and the vast majority of plants are still operated on the hit and miss principle.

The engineer of whatever plant he may be in, large or small, modern or old-fashioned, can only get the best out of it if he is himself equipped with the necessary knowledge to apply to his daily problems, and he can only obtain this knowledge by systematic study. There are still, strange as it may seem, men who take a sort of pride in the fact that they are not bothered with this new-fangled style of education, and stress the fact that they are practical engineers, who learned their business when all these studies were not required.

There has never been a time when these studies were not of value, the only thing is that there has been a time when they were not appreciated at their true value, and a man is none the less a good practical operator because he understands the theoretical side of his work. It is true that this knowledge will the sooner get him out of the necessity of performing the practical work, as he will have the knowledge and ability to carry on the direction of others.

There are thousands of men to-day who are bitterly regretting the chances they had which they were compelled to allow slip by, for the lack of the necessary education. There is no need of any one in these days remaining in that position, for even had they not the opportunity in their young days, there are lots of opportunities open to them to-day to make up for lost time.

It will be only a very few years until every town that can lay claim to the name will have a technical school, and most large towns have them to-day. In addition to these there are all the other sources mentioned in the article, and by no means the least, is the opportunity offered by the gathering together of the engineers themselves in societies for the advancement of their individual and corporate knowledge.

Working At High Pressure

IN ANOTHER portion of this issue of Power House is a description of a means of packing rods to withstand pressures which range from 300,000 lbs. to 500,000 lbs. per square inch. These pressures were necessary for the purpose of scientific investigation, and are such pressures as will never have to be contended with by the ordinary man. However, there may be something to be learned from the methods used which may be applied in part to the ordinary packing problems of everyday life. There is no question about the magnitude of these problems in the engineer's usual routine. There is scarcely a man in the power plant engineering field, unless he is a very new arrival, who has not had trouble at some time or other with a rod, that has defied every effort he made to overcome it.

The friction of packing that is screwed down too hard can be readily understood when we consider it on the light of the paper by Mr. Bridgman, wherein he shows that in the case of the high pressures used by him, the soft packing has actually cut off the steel rods used as plungers. This is accounted for by the fact that the pressure in the packing becomes actually higher than the strength of the steel, and the rod is cut off. Now, when the engineer screws down his leaky gland, on a cylinder where the pressure at the beginning of the stroke is perhaps not more than 115 to 150 lbs. per square inch, he has no idea what pressure he is exerting on the packing in the stuffing box. It may well be that the scored rods so frequently met with are as much due to actual excoriation by the packing itself as to the action of fine jets of escaping steam.

The author brings up the question of what actually causes the breakage of material, and gives instances where the breakage has occurred in a manner directly opposed to our preconceived ideas of the action of metal under a stress.

The action of glass under stress as compared to steel shows some surprising results and from his experiments generally the author deduces some theories which are of interest as to the geological formation of our earth.

While these are perhaps not exactly within the purview of the power plant engineer, they are of interest in themselves, and the article in question will well repay reading by those whose horizon is not limited to the plant in which they work.

The Operators' Point of View

WHAT IS A HORSE POWER?

By M. B. WATSON, M.E.

BEFORE THE above question can be answered exactly it must be understood just what is meant by the word "power." Power may be defined as the rate at which energy is used up in performing work, and this definition requires that we know exactly what is meant by energy and work.

Work is the effect of a force acting through a distance. Thus the British unit of work is the unit of force, the pound, acting through the unit of distance, the foot, and is known as the foot-pound.

Energy is the capacity or ability which a body or substance has within itself of doing work; and is measured in foot-pounds. Thus steam under pressure has a certain amount of energy and is therefore able to do only a definite amount of work, but if the steam is expanded, or allowed to expend its energy, quickly, it will exert a large amount of power during this short period of time; whereas if allowed to expand slowly it will only exert a small amount of power during the longer time but will do the same amount of work as in the first instance.

A flywheel revolving at high speed has a large amount of energy in virtue of its movement. If this movement is arrested suddenly an enormous amount of power is exerted during this short space of time, while if it is stopped slowly only a small amount of power is exerted over the longer time, but the same amount of work is done in each case.

The Unit of Power

The natural unit of power is therefore the amount of work (in foot-pounds) done in a unit time, (the minute.)

At the time of the introduction of the steam engine into commercial work, a unit of capacity was required by which to rate or compare these machines. This unit of capacity of an engine to do work, would naturally be the rate at which it would transform the energy of the steam into mechanical work, and therefore must correspond to some unit of power.

Previous to this the most generally used source of power was the horse, and when more power was required more horses were supplied. Thus the average person of those days could think of amounts of power in terms of the number of horses required to do certain work in certain times easier than in any other units. Accordingly James Watts conducted a series of tests to determine the rate at which a horse could do work. These tests were made on large horses used for hauling railway cars in London, and each test extended only over a short period of time, thus the results obtained were greatly in excess of the rate at which an average horse could do work over a full working day. However, Watts adopted the average of his results as a unit of power which he called the "horse-power," and which he found to be equivalent to 33,000 foot pounds per minute, or 550 ft. pds. per sec. This is the value which we still retain for the mechanical horse-power, and from the above it is seen to be quite arbitrary, for if Watts had happened to use a lighter horse our horse-power would be a smaller quantity, and as it stands it does not bear any relation to the rate at which a horse can do work continuously, although machinery is rated according to its continuous power.

We have then a mechanical horse-power defined as "33,000 foot pounds per minute;" not "33,000 foot pounds" as some people state, the latter being an amount of work or energy.

The units of force, distance and time being exactly defined by Acts of Parliament and International Agreement, we have therefore an exact value for the mechanical horse-power.

The Unit of Heat

Heat is a form of energy and can be converted into mechanical energy, or mechanical energy can be converted into heat. In 1843 and 1850 Joule performed some experiments to find the relation between mechanical energy units and heat units. The unit of heat used in this country is the British thermal unit, commonly written B. T. U., which has been defined by various writers as the amount of heat required to raise one pound of water through one degree Fahrenheit at various temperatures. The definition given as standard for power testing work by the American Society of Mechanical Engineers is: 1 B. T. U.=1/180 of the heat required to raise one pound of water from the freezing point to the boiling point, or through 212-32=180 degrees Fahrenheit. Joule, working with crude apparatus and instruments, found the relation between the above units to be: 1 B. T. U.=772 foot pounds. Recent experiments with more accurate instruments have found this figure to be inaccurate, the value accepted for lower test purposes now is 1 B.T.U.=777.54 foot pounds or 1 foot pound=0.0012861 B.T.U.

Thus a mechanical horse power expressed in heat unit rate is 33,000÷777.54=42.44 B. T. U. per minute, or 2,546.5 B. T. U. per hour.

In electrical work the unit of power is the watt, or the kilowatt=1,000 watts, and the unit of work is the unit of power exerted throughout a unit of time, or the watt-hour, or kilowatt-hour. It has been found that 1 horse-power is equivalent to 745.7 watts or 0.7457 kilowatts.

Thus 1 K.W.=1.341 H. P.=3,415 B. T. U. per hour.

Ratings

Steam engines and boilers, also electric motors are ordinarily rated in horsepower, while electric generators are generally rated in kilo-watts These ratings are supposed to be a measure of the rate at which the various machines will do work and they should bear a relation between the various types of apparatus.

Let us now investigate the method by which these various ratings are determined, also their relation to one another.

In the case of the steam engine the rated power is not the maximum power which the engine is capable of exerting, but it is about the greatest power which the engine will deliver with best economy of steam.

Various formulae have been devised for calculating the horse power of an engine knowing the dimensions of the cylinder; but since the power delivered depends on the speed, boiler pressure, type of valve and its setting, exhaust pressure, etc., none of these formulae give correct results in all cases.

Engine horse-power is measured in two ways. First the rate at which the steam entering the cylinder does work on the piston of the engine. This is known as the "indicated horse-power," or I. H. P., because in order to find this quantity it is necessary to use a steam engine indicator to show the pressure of the steam acting on the piston at each position of its stroke. Knowing the area of the piston and the length of the stroke, we can then determine the total force acting on the piston and the distance through which that force is acting and thus the

power which the steam is exerting on the engine.

The I. H. P. can be calculated by means of the following formula:

$$\text{I. H. P.} = \frac{P \times L \times A \times N}{33{,}000}$$

when "P" is the mean effective pressure (or the average throughout the stroke) of the steam, expressed in pounds per square inch pressure. "L" is the length of the stroke in feet. "A" is the area of the piston in square inches. "N" is the number of strokes per minute (double the revolutions per minute in the usual double acting engine.)

It can be seen in the above that the pressure of the steam acting on a unit area is multiplied by the area on which it is acting, giving the total force on the piston, and the length of the stroke multiplied by the number of strokes per minute gives the distance in feet through which that pressure has acted in one unit of time. Therefore multiplying all these together gives the power in foot pounds per minute. However, since 33,000 foot pounds per minute equals one horse power, we divide the product of the above by 33,000 to get the I. H. P.

The Prony Brake

The simplest method of measuring the output of a steam engine is by means of a Prony brake. Thus the output is rated in brake horse-power, or B. H. P. A Prony brake consists of a shoe or set of shoes, or series of ropes fixed to rub on the flywheel or pulley of the engine and arranged to measure either directly or through a lever the amount of force with which the flywheel trys to drag the brake along with it. Thus knowing this force and the distance the rim of the pulley moves in a minute we can calculate the horse-power delivered.

The B. H. P. is always less than the I. H. P. of a steam engine, because the steam has to supply all the power which the engine delivers, as well as overcoming the friction of the engine

In speaking of engine horse-power it should always be stated whether B. H. P. or I. H. P. is meant. The relation between these two horse-powers of an engine is the efficiency of the machine, the engine giving a greater output for a given input being the most efficient. An engine horse-power however, always means 33,000 foot pounds of work per minute, or 2,546.5 B.T.U. per hr.

In the case of electrical machinery, motors are rated in horse-power, but generators are rated in kilowatts capacity. The reason being that we are interested primarily in the output of the machine, which in the case of the motor is mechanical power, which we are accustomed to think of in units of horse-power; while in the generators the output is electric power which is measured in watts. The horse-power of an electric motor is just the same as that of a steam engine, i.e. 33,000 foot pounds per minute.

Boiler Horse Power

The mechanical horse-power is bad enough, being a purely arbitrary amount, but in the case of boilers we have worse conditions still, the boiler horse-power (so-called) having no reasonable present day relation to a horse-power of 33,000 foot pounds per minute.

Some years ago it was found by experience that 10 to 15 square feet of heating surface in a boiler would develop steam enough to supply a simple non-condensing engine of 1 I.H.P. Boilers are therefore sometimes arbitrarily rated at 1 horse-power for each 10 to 15 square feet of heating surface. If a manufacturer is selling boilers by nominal horse-power, he will likely use 10 square feet per H. P. as this will rate a given size of boiler at a higher horse-power than if he used 12 or 15.

Many government departments use various ratings and relations between heating surface and boiler horse-power for purposes of registration, inspecting and licensing boilers and engineers. The ratio is however fairly high such as 12 or 15 square feet per H. P. in order that no hardship will result to engineers, builders, etc., who have to pay fees according to horse-power of boilers or possess higher qualifications for larger units, etc.

With forced draft and modern engine condensing equipment, boilers have on test supplied steam to engines at the rate of I. H. P. for each 1½ square feet of heating surface. Thus it is seen how far from present day practice are the above arbitrary ratings. It would be more rational to rate boilers according to their heating surface instead of horse-power.

The Committee of Judges in charge of the boiler trials at the centennial exhibition in 1876 realized the inadequacy of such ratings for boiler capacity and for their purposes took the average steam requirements per horse power of the engines of that date. This average was about 30 lbs. of steam per horse-power per hour at 70 pounds gauge pressure. They assumed that the average feed-water temperature at that date was about 100 degrees Fahrenheit. Thus they arbitrarily defined a boiler horse power as the evaporation of 30 lbs. of water per hour from 100 degrees Fahrenheit to dry steam at 70 lbs. gauge. This works out at 33,460 B. T. U. per hour, or about 13 times as great as the mechanical horse-power.

Some years later in order to be able to convert horse power of a boiler operating under certain conditions of feed-water and steam pressure to compare with other conditions, the American Society of Mechanical Engineers defined the boiler horse-power as the equivalent evaporation (or about the amount of heat required to evaporate) of 34½ pounds of water per hour from 212 degrees F. to dry steam at the same temperature. This is equal to 33,479 B. T. U. per hour.

By the adoption of the report of a special committee on power testing in 1915, the American Society of Mechanical Engineers discontinued the use of the boiler horse-power as a unit of boiler capacity, except as a subsidiary unit to convert old data with new; for the reason that it is not a horse-power, and bears no present day relation to one.

Because of the fact that a boiler-horse power as above defined equals 33,479 B. T. U. per hour. and a myria-watt (=10 K. W.) equals 34,150 B.T.U. per hour, or within 2 per cent. of the boiler H. P., Mr. H. G. Stott suggested that the boiler horse-power be made the equivalent of a myria-watt. In view of the fact that a relation of this kind would be of no commercial or practical value, unless in case of evaporating water by means of electric power, or some such unusual procedure, it is difficult to see what good purpose could be served by such a relation.

The writer feels that the action of the American Society of Mechanical Engineers in adopting as the standard unit of boiler capacity "the evaporation of one pound of water from 212 degrees F. to dry saturated steam at the same temperature," is a step in the right direction, as is also the classification of boiler sizes by the areas of their heating surfaces. This would do away completely with the irrational and confusing term boiler horse-power.

In the metric system the horse-power or the "force de cheval" is defined as 75 kilo-gram-meters per second. There is also however, the unit of power called the "poncelet" which is 100 kilo-gram-meters per second. The "force de cheval" is equivalent to 0.9863 horse-power or 2,512 B. T. U. per hour. The "poncelet" to 1.351 H. P. or 3,349 B. T. U. per hour. On account of the difficulty of arranging a brake for very high power, high speed steam turbines, they are generally tested by means of the generator which they will drive, and are often rated according to the output of the combined turbo-generating set in kilowatts instead of horse-power. There is no doubt, however, that the unit horse-power will survive for many years yet and it is therefore well to have an exact knowledge of what is meant by a horse power.

DOMINION WIDE CERTIFICATE

The Editor,
Power House.

In reply to J. W. C.'s letter in January 5th issue on the Dominion Wide Certificate, in which he says a verbal examination should be sufficient without the need of confirmatory references, I do not agree with this. If this were the case a man could attend a technical school for four years and then pass for a first-class. I say and know that such a man could not even fire a boiler and would not know what a good fire was unless he had practical experience.

Let them start like I have done in the boiler house with the shovel and save their time. I have passed all exams and hold a first-class Certificate for Ontario and I started from a third class. I think a copy of the regulations for examination of engineers should be sent to him and he will see that they have to have six months in the boiler room before they can write for

fourth-class, and then one and-a-half years for third-class, two years more for second-class and five more for first-class. If a candidate has not enough experience by then he never will have. I did, and never attended a school for engineers of any sort.

The only thing I see wrong with the graded papers is that they are about eight or ten years behind in being brought into effect. Wishing "Power House" success.

S. A. W.

The Editor,

Power House.

Permit me to express my opinion on the Dominion Wide Certificate, as I have read with great interest the many comments on this subject. The idea is a fine one, if the law would be carried out properly. I cannot say as to the other cities in the province, but I can say here that in the Twin Cities of Port Arthur and Fort William, the law is not being carried out at all.

At the present time there are a number of plants being operated by uncertified men, while there are a great many men with certificates walking the streets. I would like to ask if it is necessary to report these violations to the Board of Engineers, or can these violations be handled here by our own city authorities? What steps would be considered necessary to have the law carried out?

Hoping you will find space in your valuable paper for this letter, and trusting to see a Dominion Wide Certificate.

E. J. M., Port Arthur.

The Editor,

Power House.

I have been following with great interest, the different views given upon the subject of a "Dominion Wide Certificate."

On pages 38-39 of your January 5th edition, Mr. J. W. C. expresses his opinion that the lower grade certificates, i.e., 4th and 3rd class, are not worth the paper they are written on. This may be correct, but do you not think that to a young man starting out, a 4th class certificate and later on a 3rd gives him great encouragement to go still further? Does it not encourage him to study to attain higher things? Not many things in this world are obtained in one jump. They must be gotten one step at a time.

Throughout Canada there are thousands of 4th and 3rd class engineers. Supposing these men were to find themselves without a certificate many of them would throw up engineering in disgust. I am speaking of those who are working and studying and doing their greatest to forge ahead.

In my opinion the obtaining of a "Dominion Wide Certificate" would be one of the best things for the advancement of Canadian engineers that could happen, but why not let there still be grade certificates, viz.: 4th, 3rd, 2nd and 1st?

There would be no chance of a 4th class engineer taking a 3rd's or a 3rd taking a 2nd's position if the rules were rigidly enforced by law.

What would happen to the thousands of 4th and 3rd class engineers, or those who would remain with the profession? They could take a firing job or oiling and obtain on leaving, a reference relating to their time served and good workmanship, but a reference is not so good as a government certificate. An employer or chief engineer will often give a man references who does not deserve them, simply because he, the chief or employer, thinks that it will do him no harm anyway. No, but it sometimes does the next employer harm.

A certified engineer could blow up or cause to be blown up, a boiler or do other very serious damage, but he would in all probability lose his license, nor would he again be allowed to take out another in Canada. On the other hand an uncertified man could do the same damage and get away with it. All he would have to lose would be his references at that particular position. He goes somewhere else, shows his older references, gets another job; and finishes his time, thus, after passing the examinations becomes a certified engineer.

Would this not be more dangerous than having employers and employees both protected by a certificate, even as low and worthless as the 4th class?

Engineering in Canada need not deteriorate because there are four grades instead of two

By all means let the examinations be stiffer, so that the first-class engineer has to pass an examination equal to that of the Board of Trade Certificate. The other three grades could be as hard in comparison.

H. W. W., 4th class,
Vancouver, B. C.

The Editor "Power House:"

In your issue of January 5th, I read with interest a letter signed by "J.W.C." and being of the same cloth as himself namely possessor of a British Board of Trade Certificate (1st class) but with this advantage that I also hold an Ontario Certificate (1st class) perhaps a few friendly criticisms on his egotistical remarks would not be amiss.

In the first place he makes the statement that if he cared to, he could have half a dozen certificates. I don't know to which province he refers. It certainly isn't Ontario where any engineer can tell him that one is the limit and all that is necessary to a stationary engineer.

He also states that he considers the certificates are not worth the paper they are printed on, as he knows them. I am afraid his knowledge is limited in that respect, limited to coaching firemen. I would like to see Mr. J.W.C. take charge of a plant "of any size" in Ontario without the necessary certificate. When I say "of any size" I mean a plant which requires an engineer to run it, not a fireman's job, or a plant where there is an argument as to whether it is large enough to come within the scope of the Act, or not. He would then find if the certificate was worth the paper it was printed on, provided that said plant was within the bounds of civilization and not up in the bush somewhere where it required an aeroplane to locate it.

J. W. C. lauds the value of a British B. of T. certificate to the skies, then suddenly pulls it down again by recounting his experience on board ship, whereby his chief (1st class certificate) was severely reprimanded by the super which is the experience of various boards of examiners through the province, and especially the Ontario Board. So many men with 1st class British B. of T. certificates fell down on 1st class Ontario examinations, that it was decided to let them write 2nd class, first, then if their papers were satisfactory they could go ahead with the first-class examination, provided of course the man had the required experience. A condition which I do not think unfair, taking into consideration the fact that a 1st-class Canadian certificate is not honored by the British B. of T.

J. W. C. must remember that a marine engineer's job is entirely different to that of a stationary engineer in a big plant. One is a revolution expert and the other is a C02 expert. One is fighting for revolutions and does not worry himself about trifles like furnace temperatures, or the efficiency of his boilers with regard to coal consumption, the other does, it's so many pounds of manufactured products coming out at one end of the factory to so many pounds of coal going in at the other. And there is a mighty big difference between these two engineers' jobs.

A British B. of T. certificate is only "good the world over" where British shipping is concerned, and a chief who spent his life on a 3,000-ton tramp, would no sooner expect his certificate to get him in charge of the "Olympic" than he would expect it to take him a joy ride amongst the clouds. So much for the face value of the British B. of T. certificate.

A verbal recommendaton of a man's own ability would be pretty poor dope for an examiner to work on these days. When taking it easy something more tangible than that is required. J.W.C.'s remark that one certificate should cover everything, I don't think feasible. You find "local conditions peculiar to themselves" in one province let alone the whole Dominion.

Of course we all know that things are done differently in the "Old Country;" they always were and always will be, another "condition peculiar to itself," but taking into consideration the age of Canada as a country, and the length of time these license laws have been in effect, you must admit that things are going pretty good, and if you expect every engineer in Canada to start with a 5-years' apprenticeship as a machin-

ist, well I am looking for the millenium. J. W. C. explains that he is not trying to compare the British B. of T. certificate with the Canadian one. If his whole article in that issue does not point that way, you have got to show me.

My experience has been that a great number of engineers prefer even more localized certificates than those already in existence, something on a par with certain parts of the States where they themselves would control positions vacant in a town or city.

W. J. S.

Editor's Note

This comparison of the British B. of T. certificate with the Ontario or any other provincial certificate is beside the mark, and gets no one anywhere. The question is merely whether it would be preferable to have a certificate issued by the Dominion authorities or by the provinces.

As a holder of a Board of Trade certificate (Extra First Class) I see no reason why a man that holds the Board of Trade first-class certificate should not be able to pass any provincial examination. However, it seems that there have been cases where such men have failed. There are no doubt good reasons for these failures if they could be traced. On the other hand there are men holding the first class Ontario certificate who could not pass a second-class Board of Trade examination.

When I came to this country I first settled in Montreal, which at that time issued its own licenses, in four grades. I merely asked that I be allowed to sit for the first class examination on the strength of my experience and the certificate I held, and that privilege was granted me. Some years after I sat and passed the examination for boiler inspector for the province of Quebec. If it were necessary for me to hold a certificate in Ontario I would ask the privilege of sitting for the first class examination, not on the strength of my B. of T. certificate but on my experience in Canada.

My own opinion is that a man with a first class B. of T. certificate should be allowed to sit for a first class certificate in whatever province he finds himself. I would not ask for any special privileges for such a man, but on the other hand he should not be handicapped, because he is a B. of T. man. If the man presenting himself is really the possessor of a first class B. of T. certificate it is evidence that he has served a five years' apprenticeship, not as a machinist, but as a builder of engines, and that he has also had from 2 to 5 years' experience of operating engines under far more exacting conditions than ever occur ashore. On that evidence he is entitled to at least the same consideration as the man who has graduated from the stokehold.

My argument for a Dominion certificate is that its adoption would remove all these local prejudices, and give every man the same standard of qualification all over the Dominion. I have constantly pointed out that the certificate does not make the man, it merely is an attestation of a certain minimum standard of knowledge.

There is no equality in nature, and the man with the better ability will rise inevitably. All that those of us who favor a Domininion certificate wish, is that every one should get the same start.

T. H. F.

THE STATIONARY ENGINEER AND HIS OPPORTUNITIES

Don Mack.

The field of endeavor before the stationary engineer in charge of the modern small, medium or large sized power plant has broadened wonderfully and gives a scope for individual usefulness and the introduction of economies that are hardly realized by many of us.

To illustrate, let us consider figures taken from the records of a recent convention. Ten paper mills were investigated, situated in different locations but all making the same grades of paper. The total cost of steam per 1000 pounds was 47 cents in the lowest and 91 cents in the highest. The cost of the item of coal alone varied but little more than 25 per cent. between the various mills. This, however, is but a small part of the total variation between the highest and the lowest. Special local conditions may be taken as causing a variation of 30 to 40 per cent. between the various mills, but since the highest cost exceeds that of the lowest by over 90 per cent., there is still left a large margin for investment and possible reduction.

While such study is usually allotted to the professional, consulting power engineer or specialist, there is evidently a vast field of opportunity here for the operating engineers and the members of their staffs who are in daily contact with the actual production, distribution and application of power in these plants.

In one of these mills, the power required per ton of paper produced is being reduced from 31 to 18 H. P., through a correct application of the power and a change in the process of manufacture of the product. In this case, the results are due to co-operation between those in charge of the manufacturing departments and the power plant engineer, but they are indications of the almost unsuspected opportunities for improvement which exist in more cases than most of us are usually willing to believe.

In another instance, in a plant of 12,000 K.W. capacity, each one per cent. of added efficiency over and above the ordinary development meant more than $5,000 per year saved. This, however, was a hydro-electric plant, and one per cent. in a steam plant of similar capacity would probably mean a much larger saving in dollars and cents. It is evident that in the small as well as the medium and large sized plants, fractional percentages of saving are worth while striving for and will aggregate amounts sufficiently large to compel recognition by the management of those whose efforts have been given to securing such results.

The opportunities and means available to the stationary engineers of to-day for study and self-improvement along the lines of their work are beyond doubt more numerous than ever before, and at the same time they afford a more advanced and a more thorough training than in the past in the principles and practice of the generation and handling of steam power, electricity and the production of refrigeration, compressed air, etc., as well as other lines of work with which the present-day stationary engineer is expected to have some familiarity and for the economical performance of which he is often held responsible.

The trade and technical journals, the various courses of the correspondence schools, library extension arrangements, special courses in technical schools, etc., are all facilities ready to the hand of the progressive stationary engineer who has caught a glimpse of the possibilities for greater usefulness through self-training, and who forges ahead, realizing that there is no limit to his field.

SOME CONDENSER NOTES

By J. W. Carruthers

The Editor,

Power House.

There is no one who looks forward to the issue of the "Golden One" more than I do. The articles are so helpful and the letters very interesting and especially the Questions and Answers, which I find are great fun and incidentally good practice for anyone in trying them out. There is one thing that I have particularly noticed, and that is in the description of the various plants, generators and turbines are described in detail. Switchboards and all auxiliary apparatus are explained, even the size of the various buildings and the old crane up overhead is not forgotten, and then we read in a very small paragraph that the turbines are coupled up to surface condensers, capable of handling so many thousands of pounds of steam per hour. Such an important piece of apparatus as a condenser in a turbo-driven plant is surely worthy of more consideration, than a mere assertion that such a thing exists there. I have failed to find any book, (if there is such a thing,) on surface condensers and the practical handling of them outside of the usual makers' pamphlets, and I may say that I have as good a library along the usual lines as anyone. A few notes, therefore on condensers may not be out of place.

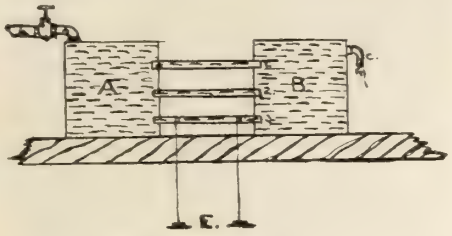
I do not think that there is a piece of apparatus in the engine room that requires more careful handling than does a condenser, and anyone knows that a careful manipulation of various valves greatly increases the efficiency of the set for obvious reasons. On the other hand any "manhandling" of these same valves, quickly leads to trouble, as was the case in a plant not a hundred miles from here. It was the custom in this plant that when any of the assistant

engineers were sick or off for any reason, for one of the repair men to take his place pro tem. While this young man was being "broke in" to the job by one of the assistants, it was particularly impressed upon him, that by throttling back the intake circulating water, the result would be a higher temperature of the condensate, which was always a very desirable point. The assistant, perhaps, forgot to mention that there was a limit to this throttling and that the vacuum carried would determine the amount. Some considerable time after, this same young man was on duty in the engine room, and about half an hour after he came on watch, the chief asked him, "How were things going?" "Great!" he said, "that so-and-so thermometer is coming up gradually since I came on."

After the chief had got things back to normal, he explained to him that it was the condensate and not the outgoing water that had to be kept high. It is only fair to mention, however, that he had got the thermometers mixed up, and had forgotten which was which.

Pitting of Tubes

For some considerable time we had trouble caused by the pittings of condenser tubes and the consequent leaking of same. On several occasions we have had to renew from twelve to twenty tubes at a time. This was an expensive operation considering the time taken for renewal and putting the condenser in working order again. The most important point, however, was that if anything should have happened to the unit then in service, it would have meant a complete shut down of the plant, our plant, then only consisting of the two units. In view of this several experiments were carried out, to determine what would be the best method of procedure under the existing conditions. Various theories were deduced such as, salty circulating water, galvanic action, chemical action, bad class of alloy in tube material, etc. About this time our Super came into the engine room one day with a copy



Test Arrangement

of the report of Messrs. Bengough & Jones', "Contributions to the History of Corrosion."

These gentlemen are I believe, experts in this particular line of endeavor, and the experiments they carried out to determine the above, are explained very clearly. Our Super told us to go to it and find out things. I have, unfortunately never seen this report in English, my copy was in French, so that the task of finding out things was even more difficult, only having had a nodding acquaintance with French. I have often read and seen these reports referred to in the technical press, so I take it that these gentlemen are masters of their craft. I shall quote them as authorities and herewith I acknowledge the source of information.

Experiment on Corrosion

Galvanic action was the base line on which we conducted our experiments. I might state here that our plant is situated on a tidal river, which is fresh low water, and salty when the tide is high. To determine the action of our circulating water on the tubes, we made out of old tins, an apparatus as per sketch. A is a tank which is connected by three tubes to a similar tank B. Circulating water is tapped from the condenser delivery pipes, falls into A, passes through the three tubes into B. and overflows at C. Tube No. 1 is a piece of unused condenser tube; tube No. 2 is the same, but tinned on the outside; tube No. 3 same as No. 1 but "earthed" at both ends.

This apparatus was kept in service for five weeks, after which the tubes were examined. It was found that tube No. 1 showed slight de-zincification; tube No. 2 also showed some signs of the same action, and tube No. 3 did not show any deterioration whatever. To make sure that such was the case, tube No. 3 was split from end to end, and examined with a magnifying glass, and

Result of an Enquiry into the Cause of the Corrosion of Condenser Tubes

Industry in which tubes are used.	Duration of service of corroded tubes.	Normal service of tubes, years.	% of tubes rejected in time of 2nd Col.	Length of tubes, Meters.	Position of the corroded region in the length.	Position of tubes in condenser.	Temperature Max. and Min. of Cir. W.	Ships; are they electrically lighted?	Protective measures.	Duration of trial. Ships Atlantic	3 years	—	3.5	3.75	Middle	All over	32° to 42°	Yes double wired	Method Harris Anderson	.....	Not defined	De-zinc. and pitting

as far as could be determined, this tube was in good condition. The three pieces of tube were cut from the same piece of condenser tube.

It might be observed here, that the apparatus as shown, does not show exact condensing conditions. This is true of course. The idea was to find out the action of the salty water on the tube alloy according to the well known law of Volta. The damaged tubes always show the de-zincification as beginning on the inside (water side) of the tubes, and not on the outside, (steam side.) It was therefore deduced that the galvanic action would show up with the above apparatus, provided that similar tubes were used with the same circulating water. That this deduction was perfectly correct seems to have been proven according to the tests made. If then, the fact of tube No. 3 being "earthed" afforded some protection, then we must "earth" our condensers. This we carried out by "short-circuiting" both condensers with ½ inch copper trolley wire. During our experiments we found that a heavy current was leaking from a nearby street railway system. This was remedied, as far as possible, by re-bonding the rails in the vicinity of our plant. After some time had elapsed it was found that an improvement had been effected by our trolley wire "earth," and to further arrest galvanic action, zinc plates were fitted in front of the tube headers and the heads themselves painted with a non-corrosive paint.

Messrs. Bengough & Jones tabulate the results of their enquiry into the cause of the corrosion of condenser tubes, in the form of a table, which is here copied complete as it contains quite a lot of information. It is to be noted, that lengths are in meters and the temperature centigrade. In a resume of their tests and to use their own phraseology—they say:

There are two sorts of corrosion, total corrosion, which attacks all the constituents of the alloy and is particularly active under normal temperature of the atmosphere. Partial corrosion acting only on the zinc. This partial corrosion must be considered as an inherent property of an alloy which is made up of zinc and copper under certain conditions of temperature and in salty water.

The brass alloys that best resist complete corrosion on the other hand offer the least resistance to partial corrosion. On the other side the protection brought about by a deposit of carbonate of lime, by galvanic action has been clearly brought out. There are four methods for practically preventing the eating away of the zinc as follows:

1. Employment of pure water for circulation.

2. Substitution of brass of a different alloy.

3. Working the condenser at a convenient temperature for the particular alloy in use.

4. Galvanic protection.

No. 1 is impossible for ship-work and is also in the most of cases equally impossible in land installations. In considering No. 2 there are several points. A brass can evidently be manufactured with a modicum of zinc, but by doing so exposes it to effects of another order. Phosphor bronze is subject to complete corrosion "Monel" metal, (copper and nickel) give the best results, but it is expensive. It is suggested that an alloy of copper and aluminum is as good and does not cost so much, but it still has to prove its efficiency.

In all cases of the alloys actually employed, the best was found to be the alloy as used by the British Admiralty, viz.—copper 70 per cent., zinc 29 per cent., tin 1 per cent. No. 3 is of particular attention to engineers. The temperature of the metal can't be lowered, because this limits the weight of steam condensed by unit surface. Shortening the course of the circulating water or by increasing the loss of the water, and keeping the tubes clear of obstructions by frequent cleaning, it is necessary to employ a filter where the water enters the system. The ratio between the weight of steam and the surface is chosen for the existing conditions without having any regard for corrosion. The use of baffle plates for the better distribution of the water over the whole length of the tubes gives favorable results.

Considered from the corrosion point of view it is better to give the water a double course and it is advisable to divide the condenser up into compartments, having an entry and an exit for each compartment. The ordinary velocity of circulating water is from M1.20, to M1.80 per second in marine installations.

It is best to adopt the higher velocity if possible. The tubes are not generally corroded if found near to the entering steam. This action is not due to foreign matter, but is, as has been demonstrated, due to the higher temperature of the tube at this point.

A Clearance Indicator

By J. C. Crichton

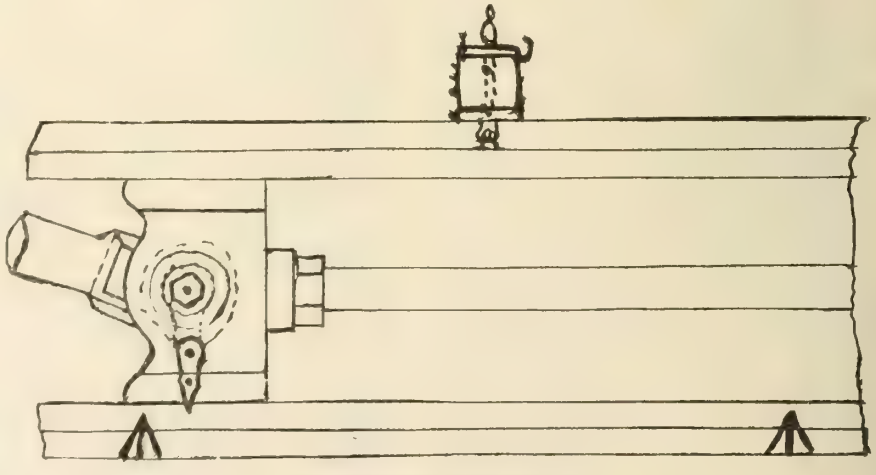
RECOGNIZING the long-felt want for a reliable method of checking up the clearance that a piston has inside a steam cylinder, I set my thinking cap on at the right angle with the result that I have made a small attachment which I term a clearance indicator.

I have been in charge of different plants with numerous engines scattered all around the plant, each one making more noise than its neighbor. Thinking possibly the clearance might be all at the one end, and the other end being pounded by the piston, I would proceed to equalize the clearance by adjusting the connecting rod. But when I would examine the crosshead and guide bars for bumping marks, I would find that every engineer that ran the engine must have put his own bumping marks on. The result is that you can't make any conclusions for the safety of the engine without disconnecting the rod and making another set of marks.

Then again if engine is fitted up with adjustable slippers, and bumping marks are put on, when they are set up the adjustments are all gone.

This attachment that I have made obviates all these difficulties, and when once put on an engine it is there for good, and remains to be seen by every engineer that comes on the job. I think if this attachment were adopted by engine builders and put on at the factory it would settle the adjustments once and for all and save mutilation of good engines. I have enclosed a sketch which will show the operation of indicator.

In the plant I am operating at present I have three engines with indicators fitted on and different engineers who have seen them enquired why didn't the engine builders put them on and save lots of worry to the operating engineer. The indicator could be made either in brass or steel and could have maker's name on it, also size of engine.



The Clearance Indicator

Renewing a Large Engine Bearing

By D. A. Hampson

A GREEN engineer in a power plant let the oil get completely out and succeeded in burning the lower half of one of the main bearings. The engine was a Ball & Wood cross compound and the main journals were 11½in. by 21in. It took the crew a couple of days to disassemble and jack up the parts so the bearings could be removed. Then it was found that the cap and the two quarter blocks were unhurt and it was only the bottom member that had to be renewed.

It was an open question whether or not to return the pieces to the factory or have a local shop do the work. Finally a decision was made in favor of the latter, because of transportation uncertainties. Our shop got the work as one best equipped, though no one locally had ever attempted a job even half as large as this one, therefore the methods followed may be of value to others in similar breakdowns.

The first move was to get the burned babbitt out of the shell. This piece, weighing about two hundred pounds, was blocked up on bricks out in the yard, setting it an angle of about 40 degrees. Thus arranged, it was possible to build a wood fire under the casting to melt out the babbitt and to catch the liquid metal as it ran out. A boy did this and had the shell clean in two hours. The old babbitt was not considered fit to put in again but was saved for unimportant work.

Shell Turned on End

Our original intention was to pour the new metal with the shell lying in its natural position, using a turned mandrel supported on parallels at a proper height at each end, and we had intended to make our mandrel out of a section of a telephone pole but we found no pieces that would answer, so had to give up that idea. The alternative was a better scheme anyway; a piece of 1-16in. sheet iron was cut the size of the face of the shell, concaved through the centre to a slightly smaller radius than the journal, and secured to the shell by "C" clamps. Then the shell was turned on end. Pouring such a bearing on end always leaves a denser, cleaner lining of the kind that shows up free from lines and holes when bored.

No ladles were available larger than the small hand type that hold about 50 cub. in. of metal, and we had to provide eight times that amount. An ordinary household iron kettle of the kind whose diameter about equals its depth, and having, besides a good bail, a ring on one side for tipping, took the place of a ladle.

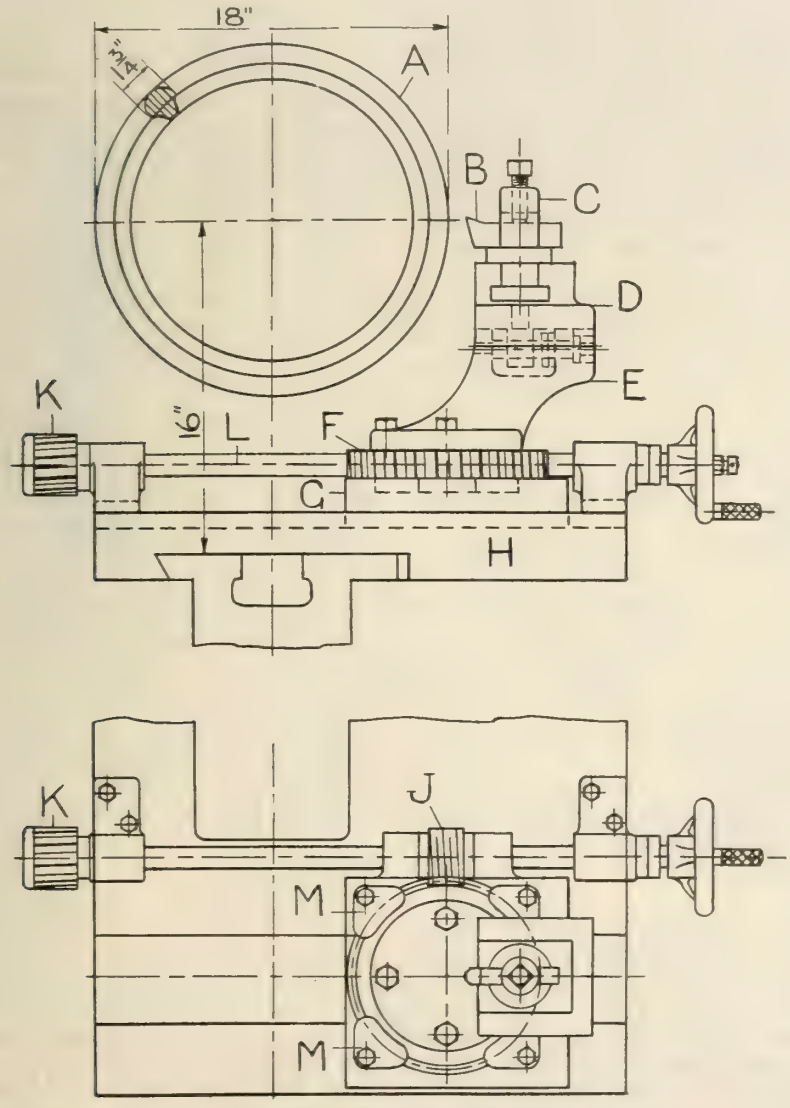
The metal was heated in the forge, near which was placed the shell standing on the concrete floor and having a good riser built up on top. A more perfect job than this equipment turned out would be hard to find. Before the babbitt had entirely cooled, workmen started to peen it, going over the entire surface and hammering the metal to a greater density and making it tighter than ever in its grip on the undercuts.

Boring Operation

Boring was the most particular of the jobs involved. We had a lathe with flaring wings on the carriage. These were "T" slotted, and we had "T" slotted parallels that we bolted to these wings to form a work table for various boring jobs. A 3in. boring bar was available, though we had to make a special tool to reach the large diameter.

It was decided that a better job would result if the three other parts of the bearing were skimmed out at the same time, removing just enough material to clean the surface. In setting up, the bottom shell was first lined up with the bar and placed at the correct height and clamped. Then angle plates were bolted to the parallels at each side of the bottom shell, forming a skeleton opening similar to that in the engine frame. The quarter blocks having been shimmed and bolted, the cap was clamped on and boring commenced.

Little remains to be told. Chipping the oil grooves was the most tedious job of all. A splendid fit and equal alignment were obtained. Three days after the parts were laid down on our floor, the work was finished. Probably the factory wouldn't have bettered this much. The babbitt used was purchased from the street railway, of a grade put out for motor bearings, and seemed well adapted for this other work.



Details of the carriage of lathe.

Babbitting motor bearings is described in detail in circular reprint No. 104, published by the Westinghouse Electric Mfg. Co., East Pittsburgh, Pa. The publication is a discussion of the production of babbitt metal by J. S. Dean, of the Railway Motor Engineering Department, and contains a number of photographs of equipment used in the manufacture of babbitt metals as well as the results of various tests of samples of alloys.

The Hydro Electric Power Commission 43 Hughson Street, Hamilton, Ont., will erect an electric station on Ottawa St., at a cost of $100,000.

C. A. S. E. Competition Questions and Answers

Question:—What shape of chimney is best? Give reasons.

Answer:—Round, because it offers less resistance to the passage of waste gases which ascend in a more or less spiral movement; whereas in the case of a square chimney, this spiral movement of the gases would set up eddy currents in each of its four corners thereby increasing the resistance.

Question:—How is the draft pressure usually measured?

Answer:—Chimney draft is usually measured with draft gauges which indicate the equivalent of water in inches, or fractions thereof, displaced by counterbalancing atmospheric pressure.

Question:—What is the correct distance between the top of the grate and the bottom of the shell in the H. R. T. boiler; also why is the distance not standardized for different boilers?

Answer:—For H. R. T. boilers it is considered good practice to have the distance from the top of the grate to the bottom of the shell at least 48 inches, varying same according to the size of boiler and furnace and the kind of fuel. For water-tube boilers it is considered good practice to have the bottom row of tubes set at least 6 feet above the grate; however, there is a tendency, because of overloading ratings and the use of long flame coal, to set them much higher. Standardization is impossible because of varying overhead requirements and difference of flame length of coal used.

Question:—Is there a standard height for a bridge wall? What are the functions of a bridge?

Answer:—There is no standard height for a bridge wall; the usual practice being 10 sq. inches per boiler horse power. The function of a bridge wall is to keep the fire on the restricted area of the grate, and the bridge wall when hot helps ignition and combustion by reflecting the heat forward to equalize with the cold air and fuel entering the furnace at the front.

Question:—Give sketch of a H. R. T. boiler giving approximate dimensions when using bituminous coal?

Answer:—Sketches made on the blackboard: Specifications diameter 72 inches, length 18 feet, set 48 inches above grate; grate 38½ square feet. The opening over the bridge wall was sufficient for the passage of the products of combustion (roughly one-sixth of the grate surface, plus the area of all the tube openings.) The combustion chamber slanted back down to the bottom of soot clean-out door.

Dimensions of main steam outlet, 6-inch feed pipe and valves, 2-inch blow down valve, 2-inch safety valves, two 2-inch pops. Manhole 11 x 15 inches. Tubes 4 inches by 18 feet.

Question:—Give a descripiton of three types of stationary grates, the reason why they are different and conditions where use is advisable.

Answer:—Straight, flat, narrow bars with narrow slots between; oval top, straight, cross-ribbed with narrow slots; flat cross ribbed (herring bone) with large slots; also grates with tapered and staggered holes. The straight, narrow bar is intended for saw dust or with either saw dust or tan bark. The flat, cross-ribbed or herring-bone with large sizes of bituminous coal. The sectional bars with tapered holes are used for hard coal screenings where forced draft is used. The herring bone is not so liable to be affected by warping as the other types of grates and gives little trouble when using the cleaning tools. Water-tube fire grates are used in connection with down draft boilers, and the circulation of water through them prevents them becoming warped or burned off by the fire in the under grate.

Question:—What fittings are standard on a boiler? What additional fittings are desirable and why?

Answer:—Water line gauges and try cocks. Steam pressure gauge and water syphon. Pop safety valve, fusible plug, main stop valve. Feed and connection with check valve, blow down valve, damper, lever and rod smoke connections including smoke box and larger doors, also various clean-out doors and fire doors.

Additional fittings: Surface blow off to skim organic substances from surface of water in boiler, soot blowers to blow off the soot from water tubes and the inside of fire tubes. CO2 recorder to indicate the relative combustion efficiency. Pressure and temperature recording instruments to further check up the efficiency. Also automatic damper regulator or, better still, automatic draft and damper regulator because higher efficiencies are obtainable than with hand regulation of either.

Question:—Why is it necessary to have a damper in each boiler? Describe desirable position for damper rod and method of graduation for damper opening?

Answer:—To regulate draft and thereby rate of combustion and evaporation. The desirable location of the damper rod (control lever) is at or near the front of the boiler and readily accessible. The damper rod may be graduated by marking intermediate points between the positions of full-shut and full open.

Question:—Give description of three types of boiler feed pumps and their individual advantages. Why is an injector not usually used except in emergency?

Answer:—Plunger, single acting duplex, rotary pumps. Rotary pumps may be either power or turbine driven, but have a much lower efficiency than the plunger type pumps. However they have advantages of handling very hot water and of lower cost and maintenance. While the duplex are more complicated than either the rotary or single acting pumps and require careful valve setting and more packing and adjusting, they create less shock to the boiler feed pipe, fittings and boiler, and when acting against high pressure the efficiency is much higher than either the single acting or rotary pumps.

An injector is seldom used except for emergency, because its efficiency compared with a regular feed pump or a H. P. steam trap is low; also it will not handle very hot returns or feed water, nor can it be used where there is considerable suction lift.

Question:—What is the function of a blow down valve? Cite some of the requirements of a blow down valve. Cite some of its weak points commonly met with.

Answer:—To lower the water level occasionally and thereby keep the sediment from the bottom of the boiler, and to empty the boiler when required.

Blow down valves should work freely and yet close tightly to prevent loss of hot water, and they should be made strong to sustain shock. There should be a combination of two valves always. Some valves fail to seat because of sediment lodged under the seat. Others tend to stick and are liable to be broken when forced open, and still others are leaky and corroded.

PULVERIZED FUEL BULLETIN

A new bulletin on the Quigley Fuel Systems, comprising methods of preparing, transporting, and burning of pulverized fuels has just been published by the Hardinge Company, 120 Broadway, New York.

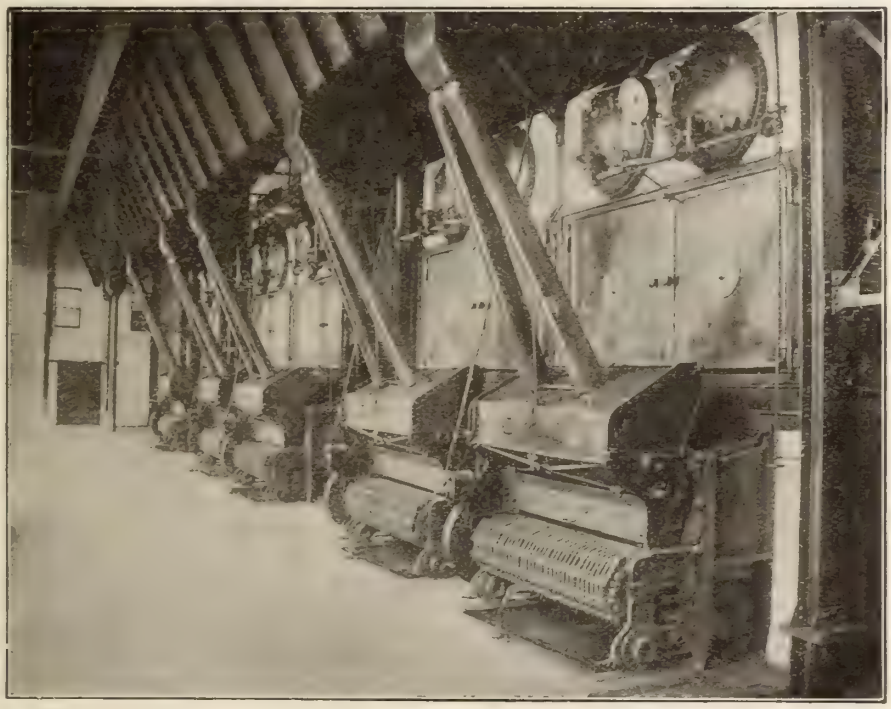
This bulletin is known as No. 12 and treats the subject of pulverized fuels in a manner never before attempted. One of its distinguished features is the fact that emphasis is laid upon the methods employed to properly prepare and burn the powdered coal, rather than occupying most of the space discussing the pulverizer.

This bulletin comes at a very opportune moment, for the burning of pulverized fuel has reached the stage in its development where its success is assured. It is now being specified by the largest power and heat engineers in the country as a solution to many problems involving the generation of heat.

Aside from complete plant layouts, what they term as a "Unit Milling Plant" is described. This layout is radically different from anything ever before developed. The system comprises a method of pulverizing and transporting the coal to one or more furnaces and continuous operation over extended periods.

This catalog will undoubtedly be very useful to the engineer designing power plants or furnaces requiring considerable quantities of heat, as facts and figures are given which will aid him in his work. At the same time, it is written in a way that will interest the non-technical person who is seeking a general knowledge of this most interesting and talked-of subject.

"B & W" STEAM BOILERS



Marine and Land Types

Installation of "B & W" Boilers and Mechanical Stokers at the Acadia Sugar Refinery, Dartmouth, N. S.

"LAGONDA" BOILER TUBE CLEANERS

Keep tubes free from scale. Driven by water, air or steam and designed for all tubes over two inches in diameter.

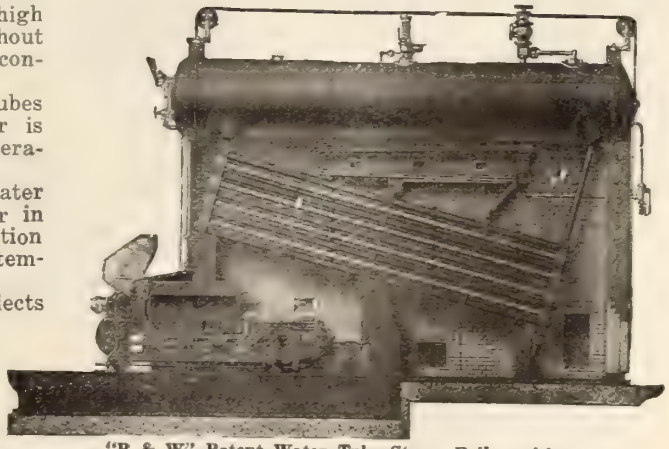
Entirely Devoid of Unequal Strains

All joints of B. & W. Boilers are removed from the immediate action of the fire. There are no unequal strains —no weak spots. You can gain high pressure with rapidity and without danger. Note these features of construction:

1.—A series of Inclined Water Tubes over furnace in which water is quickly raised to high temperature.
2.—A Horizontal Steam and Water Drum which keeps the water in rapid circulation in one direction and maintains a uniform temperature.
3.—A Mud Collector which collects all foreign matter.

B. & W. Stationary and Marine Water Tube Boilers are easy to clean, easy to erect and are as durable as boilers can be made.

Our catalog gives complete technical information. Shall we send it?



"B & W" Patent Water Tube Steam Boiler with Superheater and Mechanical Stoker

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

STEAM PER HOUR

Question:—Can you tell me the amount of coal that would be required to supply a drying room with steam under the following conditions? There is a live steam line of one inch diameter from the boiler room, and in the room there is a 6 inch pipe about 38 feet long. This pipe is reduced to ¼ inch at the end and the end is left open. The boiler horse power is 140.

Answer:—The boiler horse power does not affect the above question, but what would have more bearing would be the steam pressure. The amount of steam required per hour can very easily be determined with the lay out as given above, by simply catching the water of condensation and weighing it for one day, and then taking the average weight condensed p.h.. This would give the amount of steam used per hour, and the average evaporation per lb. of coal would give the coal required. If the steam is allowed to blow freely through the ¼ inch line there will be an unnecessary waste of steam. If we assume that the boiler steam pressure is 100 lbs. per square inch gauge, and that there is a drop from boiler to the end of the 6 inch pipe of 10 lbs. then we should have a pressure of about 90 lbs. per square inch at the ¼ inch pipe. We can then figure approximately the weight of steam escaping per hour from an opening of this size and at the pressure assumed. We can use Napier's formula, which is that the weight of steam that will escape through an orifice of one square inch in area is in 70 seconds just equal to its gross pressure. Then in one second it will be equal to 1-70th of this and in one minute 6-7ths. In formula form we have:

$$\text{Weight of steam per min.} = \frac{P\ A\ 6}{7}$$

where P is the gross pressure and A the area of opening.

Applying this to the problem in hand we have

Weight of steam per hour

$$= \frac{P\ A\ 6 \times 60}{7} = \frac{105 \times .049 \times 60}{7}$$

$$= 308.7 \text{ lbs.}$$

If each pound of coal as fired will evaporate 7 lbs. of water then the coal required will be

$$\frac{308.7}{7} = 44.1 \text{ lbs. per hour}$$

COMBUSTION BY OBSERVATION

Question:—I am firing a h.r.t. boiler, and am doing my best to get efficiency without the help of any instruments but a draft gauge, and what I can observe by the state of the fire and the results it gives. I have noticed that when the coal (Pocahontas) gives a long yellowish flame, the admittance of air over the fire causes the flame to shorten and become more nearly white. Is all combustion finished when the flame is ended as in the case of a short white flame and no smoke from a hot bed of coals? Can you tell me from this explanation how I should handle my fires to get the best results.

Answer:—The coal you are using is a semi-bituminous with a high carbon content and about 18 per cent. volatile matter in the combustible, and a heating value of about 15,000 B.T.U. This coal closely resembles Welsh steam coal in its analysis, and should be handled the same way to get the best results. What is required is to first distill the gases and ignite them by passing them over a hot fire, and afterwards to burn the remaining solid carbon. In order to do this on a hand fired grate a fairly thick fire should be maintained, and when fresh coal is put on it should be kept to the front of the grate, leaving a portion of the fire towards the bridge wall with no green coal at all. The coal will give off the gases or volatile matter and these will ignite and form a flame which will be yellow if not properly mixed with air, but which should be short and brilliant if the proper amount of air is being admitted. After the green coal has finished giving off this flame, it should be pushed back over the fire with a rake, taking care not to disturb the lower bed which will be composed of burnt coal and ash, and must not be mixed with the good coal on the top of the fire. A certain amount of smoke will be given off when the green coal is first put on but this is unavoidable and not to be greatly worried over. With this kind of coal the fire should be kept at least eight inches thick and twelve inches will give good results. Put a good charge on when you fire, and leave it as long as possible without disturbing it. Push the front back and slice occasionally but with care, and you will get good results. The writer has seen a boiler fired with Welsh coal where a fire was only put on once an hour.

Air should be admitted over the top of the fire while the distilling process is going on, but closed while the carbon is burning. The ventilators in the fire doors will give all that is needed as a rule.

Engineering News

The city council of Sydney, N.S., plan alterations and improvements to water works to cost $150,000.

The Dake Engine Co., Grand Haven, Mich., manufacturers of the Dake Engine, have opened a Canadian office at 45 Adelaide St. E., Toronto, Capt. Wm. Stitt is in charge of the new office.

The Ontario Creameries, London, Ontario are in the market for complete refrigeration and ice making equipment. About $30,000 of equipment will be purchased.

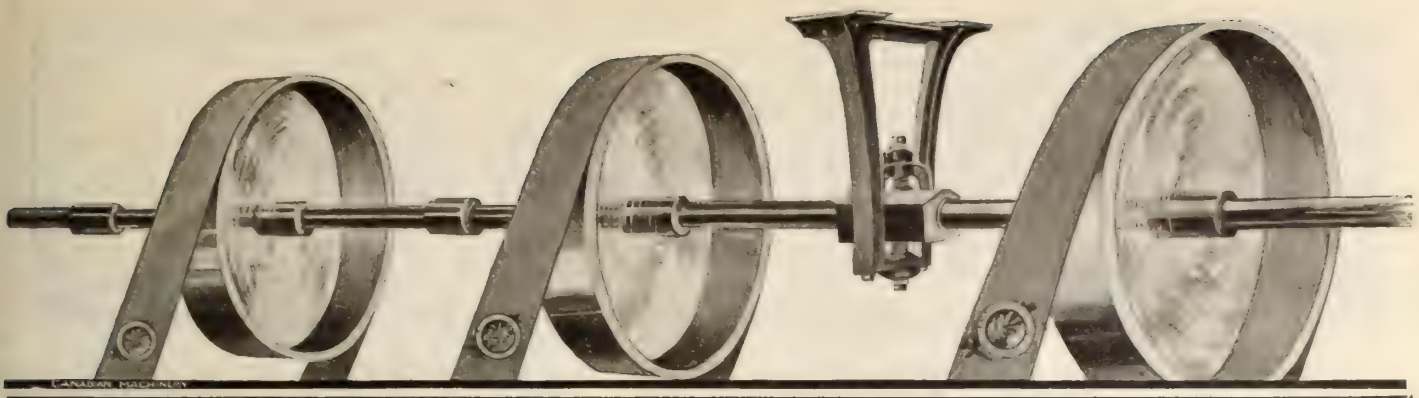
The city council of Merlin, Ont., plan electric lighting and power distribution to cost about $28,000. Similar plans are being made by the council of Walkerton, Ont., to cost about $40,000.

The city council of Wiarton, Ont., plan improvement to water works pumping, plant including the installation of an electric operative pump, and a large gasoline engine. Prices wanted on equipment. About $25,000 will be spent.

Charles Barber & Sons, manufacturers of turbines and power plant equipment, Meaford, Ont., have been sending their friends in the trade a very neat calendar for the New Year. The illustration is a reproduction of the famous picture of Canada's first parliament under Confederation and is most appropriate in that the Barber firm began business in this notable year, 1867.

In 1919 there was published by the Engineering Station of the University of Illinois a bulletin, No. 111, dealing with the forms in which sulphur occurs in coal. The research work in connection therewith was conducted in the Chemical Laboratory of the University of Illinois by S. W. Parr and A. R. Powell, who developed successful methods for determining quantitatively the different chemical forms of sulphur in coal.

By the end of January it is understood that the island plant (Fort William) of the Canada Starch Co., will again be operating at full capacity and employing a full staff of 220 employees. As is usual during the months of December and January, the plant is closed for general repairs and stock taking but it is stated that orders are plentiful and when the plant starts next month it will be operated without interruption.



D. K. McLaren's Leather Belting Makes Drives Efficient

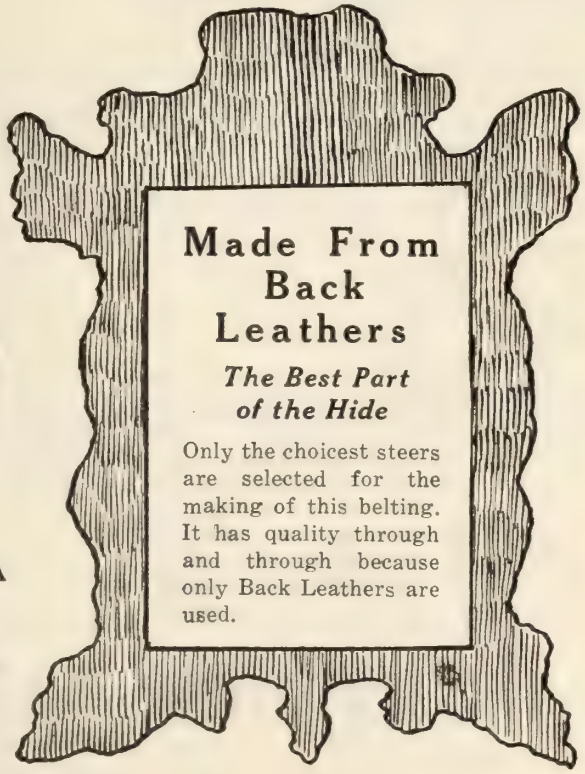
WHEREVER you see the Oak Leaf trade mark stamped on a leather belt in use you know the owner is getting really dependable and economical belt service. D. K. McLaren's Genuine British Oak Tanned Leather Belting gives this cheap service because it is made from the best leathers obtainable—tanned in the best way known. And Canadian users know it.

Every day, plants are giving D. K. McLaren's Leather Belting a trial and then adopting it exclusively; for in actual test they find all our verbal arguments true.

They find it so tough, pliable and stretchless that practically all power is put to use. If any is wasted it is inconsequential. Due to Oak Tanning this belting lasts long.

Oak Tanning

Every D. K. McLaren Belt is tanned by the celebrated English Oak Tanning process. It adds pliability to the original strength of the hide.



Made From Back Leathers
The Best Part of the Hide
Only the choicest steers are selected for the making of this belting. It has quality through and through because only Back Leathers are used.

Showing magnetic polarities with different direction of winding and different direction of current.

DIRECTION OF WINDING DETERMINES THE POLARITY OF A MAGNET

(By C. O. Jackson)

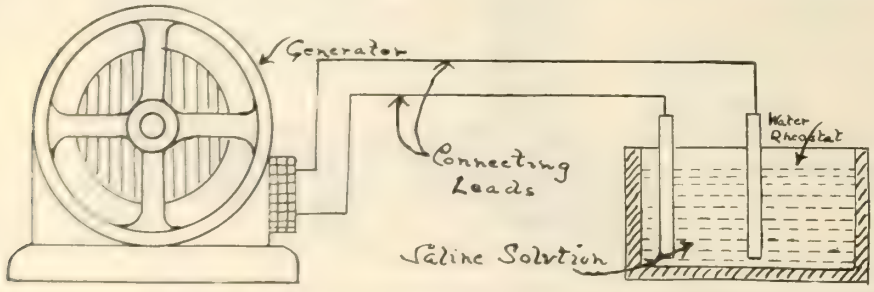
(Copyright—All rights reserved)

The effect of change of direction of current through the winding of an electro-magnet, or by change of direction of the winding is explained graphically by Fig. 1. It will be noted (see I, II, III, and IV) that there are four possible combinations. Thus the polarity is determined by two factors:—(A) the direction in which the coil is wound, that is, the direction in which the hand moves in winding it on, and (B) the direction in which the current is circulated through the coil. Application of the right-hand rule will verify the polarities specified in the illustration.

DRYING OUT GENERATORS

(By Robert Smith)

Probably the most effective method of drying out a generator, the windings of which have become damp in transit or from some other cause, is to short-circuit its armature on the line side of the ammeters and operate the machine with a very weak field, so adjusted that the temperature of the windings will not exceed possibly 65 deg. C. or 149 degrees F. Care should be exercised not to overheat the windings, because the temperature of the inner parts is likely to be considerably in excess of that of the exposed parts. Another method of drying out is to use a water rheostat for a load, as shown in Fig. 1, whereby the armature current may be adjusted.



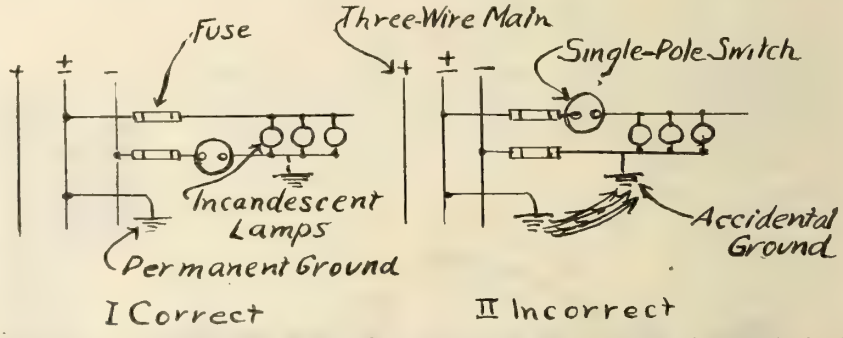
Arrangement of water rheostat for drying out generator.

ELEVEN OHMS AS THE RESISTANCE OF A CIRCULAR MIL FOOT OF COPPER WIRE

(By L. R. Grant)

(Copyright. All Rights Reserved.)

The resistance of a cir.-mil ft. of copper is determined by the purity of the copper and on its temperature. The resistance of ordinary commercial soft-drawn copper wire at 70 deg. Fahr. is almost exactly 10.6 ohms. However, the use of the value of 11 ohms in most formulas is justified. In computing wire sizes for interior wiring circuits, it is folly to endeavor to figure too closely. The length of the circuit is probably not known within ten per cent., the purity of the copper to be used unknown, and finally, one must use conductors of one of the standard wire gage sizes. Hence it is common practice to use the 11-ohms value, given above, in practical calculations. The result obtained by using it will, on the average, be as accurate as those obtained by using 10..6 ohms, and it is an easier figure to handle. Also the value "11 ohms" can be memorized readily.



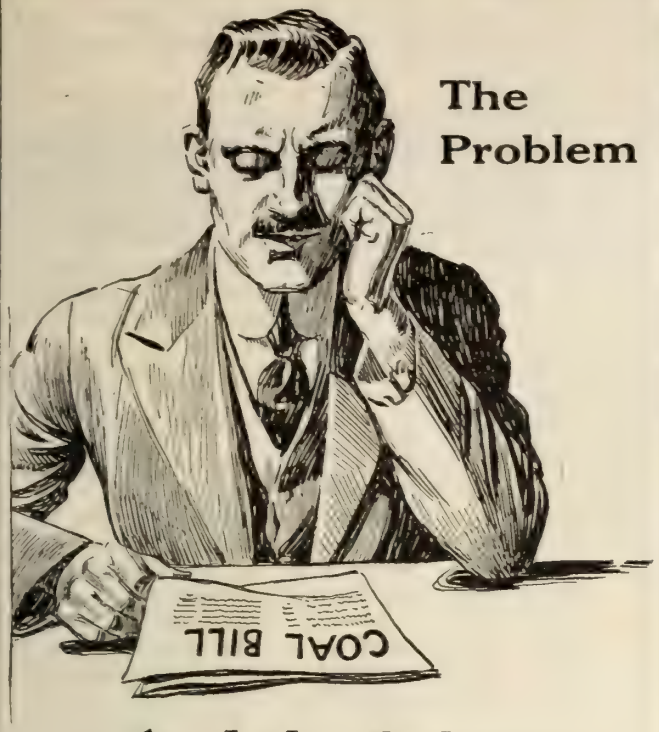
Correct and incorrect methods of installing single pole switches in two wire branch circuits feeding from three wire mains.

SINGLE-POLE SWITCHES FOR THREE-WIRE BRANCHES

(By J. W. Carter)

(Copyright. All Rights Reserved.)

When a single-pole switch is cut in a branch-circuit wire which connects to the neutral, a short circuit current, as shown at Fig. 1, I, may flow (regardless of whether the switch is "open" or "closed") if there is a ground on the side wire of the branch circuit. The neutral wire of a three-wire system is, as illustrated, always grounded. Where the switch is cut in the wire, which does connect to the neutral (Fig. 1-I), such a short circuit current cannot flow when the switch is open.



The Problem

--And the Solution

Leaks in the boiler room that lead up to top-heavy coal bills are a problem demanding quick action from every plant executive. The permanent solution is BAILEY **Boiler Meters.** On easily-read charts they point out poor conditions and enable the fireman to quickly find a remedy.

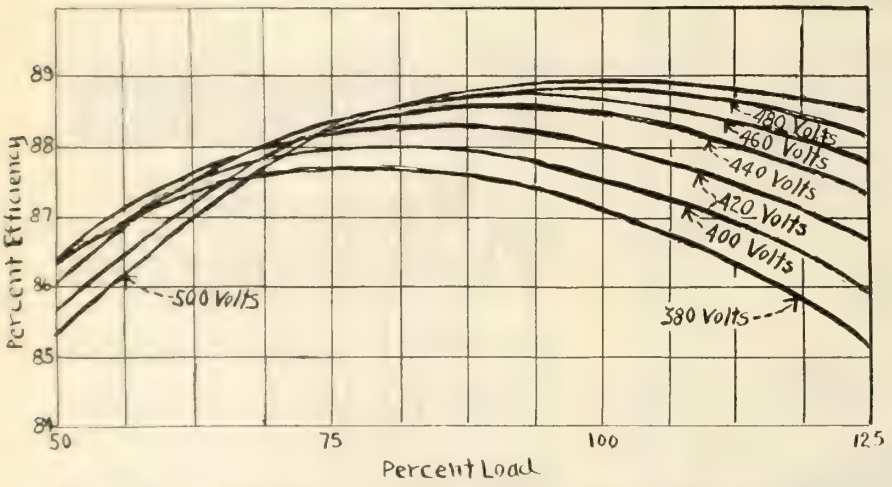
EFFECT OF OVER AND UNDER-VOLTAGE ON A THREE PHASE MOTOR

By W. A. Brown

(Copyright All Rights Reserved)

The accompanying graphs, Figs. 1 and 2, and the following table give typical performances (Westinghouse Electric & Manufacturing Company's data) which result when a 440-volt 3-phase-60-cycle induction motor is operated on voltage above or below 440. It will be noted that the power factor decreases as the impressed voltage is increased. The efficiency decreases as the voltage is increased at partial loads but above about three-quarters load the efficiency increases with the voltage.

	Per cent, Efficiency Per cent. Full Load				Per cent. Power-Factor Per cent. Full Load			
Volts	50	75	100	125	50	75	100	125
380	86.35	87.7	87.05	85.1	84.8	90.2	92.2	93
400	86.3	87.92	87.5	85.85	82.8	88.8	91.4	92.5
420	86.35	88.18	88	86.7	80	87.5	90.4	92
440	86.3	88.22	88.46	87.3	77	85.5	89.2	91.2
460	86	88.3	88.6	87.8	73.8	83.3	88	90.4
480	85.68	88.22	88.8	88.15	70.2	80.8	85.8	88.7
500	85.3	88.2	88.87	88.5	65.4	77.0	83.7	87.2



Graphs showing relation power factor and load of a 440-volt, 3-phase induction motor operated on different voltages.

LIGHTNING'S BETTER FEATURES

We hear innumerable stories about the depredations of lightning and have learned to look only on its bad characteristics such as striking telegraph wires and killing line men fifty miles away or following the power line down into a coal mine and setting off the dynamite chamber, but we seldom think of it as a benefit to mankind, but it has been known to have remarkable restorative properties in cases of incurable disease. In Connecticut a woman who was as deaf as a lamp post had her power of hearing restored in a marvelous way. To penetrate to where this woman was in her house the bolt had to shatter several rafters, pass through two floors and demolish windows and frames before reaching her body. She became unconscious and was badly shaken up, but upon regaining her senses was well able to hear.

A case somewhat opposed to this but equally as remarkable was that of a man who had been afflicted with paralysis from infancy and who was struck by lightning and rendered unconscious for a short time, but after recovering from the shock he gradually regained the use of his limbs but was permanently deaf.

A woman who had been paralyzed for thirty-eight years was struck by lightning and cured.

Another woman who had paralysis of the vocal cords which rendered her speechless was struck by lightning and whether it was the lightning or the fright, she screamed and has since had the use of her tongue.

Many miraculous cases are recorded of people having their shoes and clothing torn off by lightning while receiving no bodily harm.

Another point worthy of note is that there is no record of anyone ever being struck by lightning while sitting in an automobile. This is probably due to the fact that rubber tires act as non-conductors, and unless the car is submerged in water, or the tires are deflated so that the rims form a contact with the ground, there is not the slightest chance of a car being struck by lightning.

BULLETINS

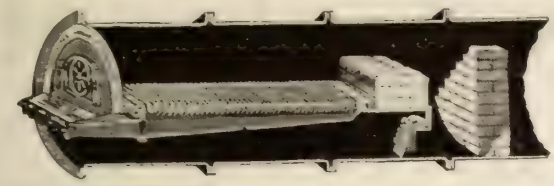
The American Steam Gauge and Valve Manufacturing Co. have issued a bulletin describing their American Recording Thermometers. These instruments are made for a variety of temperature conditions, up to 1000 degrees Fahrenheit. The bulletin which is in folder form fully describes this new line.

The National Meter Co., New York, have issued a bulletin describing their Empire Oil Meters for fuel and other oil measurement. The bulletin shows illustrations of all the parts of the meters, which are numbered, and a corresponding numbered list.

At the Southern Experiment Station of the Bureau of Mines, Birmingham-Tuscaloosa, Ala., determinations have been made as to the relative combustibility of different cokes in a brick combustibility furnace. Further work was done with the shatter and friability tests, and the true and apparent gravity determinations are practically complete. Float and sink tests have been made on a sample of coke breeze submitted by the Sloss Sheffield Company to determine if sufficient ash elimination could be obtained to make feasible the mixing of cleaned coal with raw coal before carbonization.

The sampling of coals from the mines of Carbon County, Utah, has been completed by the Bureau of Mines. A bulletin on the analysis of Utah coals generally is being prepared for publication.

The TURBINE Furnace



First Set Accepted and Another Ordered

Result of Tests of P. Burns & Co., Vancouver

A No. 3 Boiler with "Coalmont" Run of Mine on Shaker Grates before TURBINE FURNACE was installed. With "Coalmont" Slack after installation. Return Tube Boiler, 144 H.P. H.S. 1440 Sq. Ft. 12 tests taken.

	Before	After
Equiv. Evap. per hour	4363.5	5261
Boiler H.P. developed	129.3	171
Evap. per Lb. of fuel from & at 212° F.	6.82	7.82

RESULT—Notice that for equal outputs less Slack is used than Run of Mine previously. Thus the saving is Greater than the difference of the two fuels.

If you burn high grade coal in your heating plant, why not install a set of TURBINE FURNACES and burn slack, sawdust, etc. Enquiries solicited.

Canadian Association *of* Stationary Engineers

This Organization is founded on the following principles:

—The better education of its members in the science of steam engineering.
—To protect the competent engineer and his vocation.
—To enroll all competent engineers in this organization.
—To impart information beneficial to the profession.
—To assist members out of employment to obtain the same.
—To procure by legal enactment greater safety in the operation of steam plants.
—The belief that knowledge and ability of one's profession is what is necessary to make success possible.

Brother Engineer:

Did it ever appeal to you to join an association devoted entirely to the interests of the engineering profession; one which by means of lectures, illustrated and otherwise, delivered in the lodge room, tends to keep its members right up to the minute with the progress made in the engineering professions?

If you are interested in an association of this kind, and live where less than fifteen engineers reside, send for a copy of our constitution, and make application to the nearest lodge for membership. If you live where more than fifteen engineers live, get together and send in a written application to me.

The undersigned will be very pleased to give any further information required.

F. HARPER, President Grand Lodge.
89 Bay Street,
Kingston.

L. J. ELLIS, Sec.-Treasurer Grand Lodge.
142 East Avenue, N.
Hamilton.

Was the New Cabinet Made in Montreal?

THE SECRET of the Cabinet is out. J. K. Munro, whose observations on what goes on behind the scenes in Ottawa have amused, entertained and instructed readers of MACLEAN'S in recent years, "explains" what happened when Premier Mackenzie King endeavored to pick his own Cabinet members.

Of course you will want to read this "inside" story of Canadian politics in

MacLean's Magazine
for
February 1st

which is on sale at all news-stands to-day.
This issue also includes several timely and authentic articles on subjects of national importance to Canadians, as well as a particularly attractive list of entertaining fiction, and a generous measure of Reviews.

Here's the "Inside Story"

According to Mr. Munro:

"Crerar had read the King proposals to his Western Progressives assembled at Saskatoon, and had so far received their approval that he was on his way East, presumably to close the deal.

"Then something happened. Sir Lomer Gouin and Senator Dandurand are represented as visiting Ottawa and turning the Liberal leader's plans topsy-turvy." Mr. Munro goes on to say: "The Cabinet slate had been smashed. . . . . A different reception had been prepared for the Hired Man's Hero. . . . . What did the little Quebec Boss do in those three hours? Well, report says that he went straight to the Rideau Club, where the young Premier-to-be was waiting for him in the 'Silence Room' (that said silence was so rudely shattered that a frightened waiter crept up and closed the door); and that behind that closed door an embryo statesman had it made plainly evident that the powers that made could unmake; and that a Quebec that had given him a sullen support would rise and rend him unless he listened to her voice—and Sir Lomer had Quebec's voice about his person."

READ THESE FOR INFORMATION:

THE WEST WON'T STAY DOWN —by Charles Christopher Jenkins: The second of two up-to-the-minute articles showing how the Canadian West is meeting its [illegible] agricultural, financial, economic, commercial and social problems in these days of stress and strain.

FAR NORTH REALLY LIVABLE —by Vilhjalmur Stefansson: Canada's foremost Arctic explorer gives facts and figures to prove that life in the Land of Winking Night can really be pleasurable and profitable.

THAT MAN FROM CARSTAIRS— by Nicholas North: A breezy, informative sketch of Henry Wise Wood—formerly "That Man from Missouri"—who wields such a potent influence in Albertan politics.

SLEUTHS OF THE WILDERNESS —R. G. MacBeth: A series of fascinating — and true — tales of Canada's famous red-coated force, and how offenders are tracked for months and years, by the Dominion's relentless, tireless preservers of peace in the wilds.

AND THESE FOR ENTERTAINMENT:

A PRIMROSE AND A PROMISE —by Margaret Busbee Shipp: A light little love-story which commences on a continental train, progresses through the tulip hills of Holland, and culminates in an international hockey match.

THE SAIL-DRAGGER—by Frederick William Wallace: A melodrama of the sea; which includes a pretty typist, a brawny hero, half a dozen Bolsheviks and a mysterious will,—all the ingredients of a fascinating "thriller."

HOW "BOB'S MAGGIE" GREW INTO HER JOB—by Ethel M. Chapman: The fascinating and adventurous life-story of Dr. Margaret Patterson, Toronto's new Police Magistrate.

ON THE JOB — by Archie McKishnie: "The Swallow" decided to go straight, but found many influences endeavoring to force him once again into the influences of the underworld. Mr. McKishnie, as usual, has a strong "twist in the tail" in this yarn.

MOSTLY SALLY—by Pelham Grenville Wodehouse: Some more about Sally and her fortune, and Ginger and his foibles.

THE HOUSE OF APPLEDORE—by "Sapper"—H. C. McNeile: "The Writer's Story": how a journalist was imprisoned, how he faced death, and how he used a clever code to escape.

ODETTE ELOPES—by Margaret Hilda Wise: A simple little tale, entertainingly told, of a girl who announced her elopement.

Besides all of this, the **Review of Reviews Department** gives a review of world-wide matters of current interest that alone is worth more than the price of the magazine.

EQUIPMENT

For Sale—Steam Plants

1—Complete plant, consisting of two 72" x 18' boilers with tandem compound Corliss Engine, belt, etc., complete.
1—plant consisting of 72" x 18' boiler with 100 H.P. automatic engine complete.
Box No. 27122 P2H

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 100.

FOR SALE—STEAM PLANTS—1. COMPLETE plant consisting of two-72 in. x 16 ft. boilers with tandem compound Corliss Engine, belt etc., complete. — 2. Plant consisting of 72 in. x 18 ft. boiler with 100 H.P. automatic engine complete. Box No. 27122, Power House. P2H

FOR SALE—45 K.W. Edison D.C. 125 V. Dynamo, 1050 R.P.M., with rheostat and spare armature. In perfect condition and can be seen running up to about end of January. Board of Trade Building, Montreal. Price $250. Apply Superintendent.

FOR SALE — FORTY HORSE-POWER VERtical Boiler 120-lb., steam, Ontario inspection, 129-2" tubes 5' 9" long, 74 of them new. Complete with grates, smoke stack and cast iron base. $500.00 F. O. B. Port Arthur.
Return Tubular Boiler 72" x 18' for 115-lb. steam, Ontario inspection, 84-3½" tubes, straight seams, triple rivetted butt joint. This boiler with full flush front and doors, arch-plates, soot doors, but no grates or fittings, for $900.00 F. O. B. Port Arthur. Port Arthur Boiler Works (pj1h)

SITUATIONS WANTED—MALE

ENGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821, Power House. p.2.h.

INSTRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any province, stationary or marine. Terms and particulars on application. Box 13921, Power House. Ph2

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House, P2H

STATIONARY ENGINEER—SECOND CLASS, requires position, ten years' experience of steam generation, refrigeration, cold storage and electric generation, thoroughly experienced with heating systems and hydraulics and all classes of stationary engines, used to large plants, good references. Apply to Box 5122. P.3H.

SITUATIONS WANTED

STATIONARY ENGINEER DESIRES POSItion as engineer or fireman. Holds second class certificate, 20 years experience. Apply to Box 151121, Power House.

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work —A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

The "Unific" does not readily corrode It resists extreme changes of temperature and withstands the highest working steam pressure.

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

Do You Have Trouble

Keeping Turbine Blades Clean?

YARWAY BOILER SKIMMER

Succeeded after Other Methods Failed in These Cases

Where turbine engines are used, it frequently happens that a fine sediment is carried over by the steam and burns on to the turbine blades, even while the boilers remain free of scale. The YARWAY BOILER SKIMMER (a continuous, circulating surface blow) has ended this trouble in a number of cases, two of which are cited below.

The Lakeside Paper Company, Neenah, Wis., in a letter from Mr. William C. Nash, Superintendent, says:

"Before using the Yarway Skimmers, we had trouble with our turbine engine, due to the fact that the steam carried along a considerable deposit of foreign matter, which attached itself to the blades. After installing the Skimmers, we found that they took out all of this matter, so that we have no further trouble from this source. We also find that it is not necessary to blow down the boilers as often as before."

The Lakeside Paper Company has had all of its boilers equipped with YARWAY SKIMMERS for nearly three years.

The Standard Silk Company, Chadwicks, N.Y., have had two YARWAY SKIMMERS for a year and a half. Although they use an expensive purifying system on their feed water, they were troubled by a fine precipitate that passed over with the steam and burned on to the turbine blades. Frequently it was necessary to scrape the blades between Saturday night and Monday morning to keep the turbine in running order.

The engineer now reports that since installing the YARWAY SKIMMERS the turbine blades have remained clean and bright without scraping.

The YARWAY BOILER SKIMMER has been successful in eliminating scale in many cases where other methods have proved ineffective. Details of its operation are interestingly told in Bulletin S-1201-A; where shall we send your copy?

For Real Plug Cock Valve Service

Standardize on

HOMESTEAD

Quarter-Turn Valves

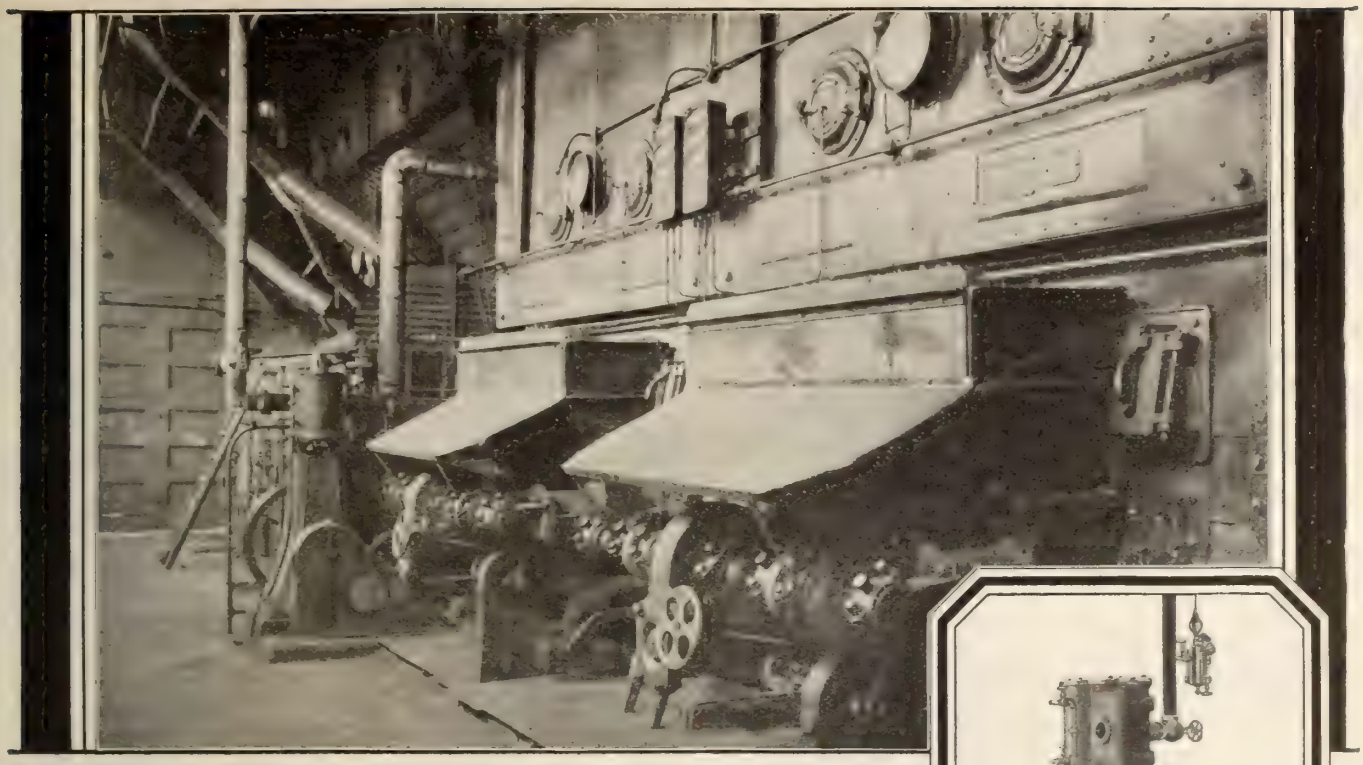
After all plug cock valves are the real thing for every service. Their superiority over Globe, Gate and elaborate designs is as well known as their age. And of all in use today, **Homestead Quarter Turn Valves** are the most outstanding.

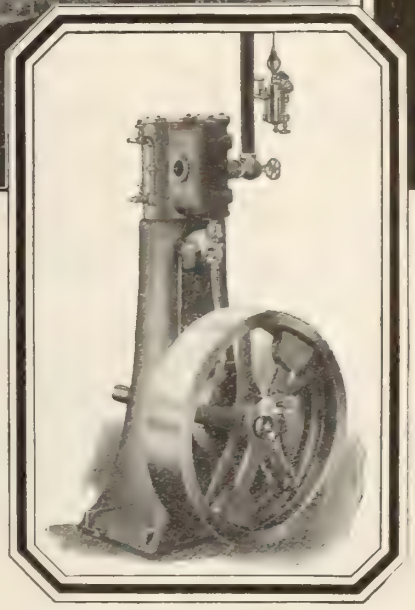
In Homestead Valves the plug cock provides a straightway opening, very important in high pressure service. They are easy to operate, the plug cock closing by a **quarter** turn. Made in two, three and fourway types.

There are many other features fully described in our catalogue. Write for a copy today.

Homestead Valve Mfg. Co.

Homestead, Pa., U. S. A.





Reliable Steam Power at One-Half the Usual Cost

With every frictional surface running in oil as a result of automatic internal lubrication by pump and *gravity* flow, "Sirocco" A B C Vertical Steam Engines assure long-continued service—year after year.

Economical because their steam consumption is one-half to two-thirds the prevailing rate, and because the oil required is about one-fifth the usual amount, "Sirocco" A B C Engines are particularly adaptable for the operation of stokers, generators for lighting plants, centrifugal pumps, and fan installations.

Because they are small and compact, "Sirocco" A B C Engines may be located within confined spaces where ordinary steam units could not be used because of their size.

Then, too, with "Sirocco" A B C Engines there are not the usual objections associated with ordinary steam units, such as wastefulness and the need for frequent adjustments and resulting shutdowns.

Many "Sirocco" A B C Vertical Engines have been giving continuous service 24 hours a day, year after year, the only attention required being filling the oil reservoir and taking up the bearings about four times a year.

If you have a job for a small steam engine—where economical, continuous operation is demanded—write for complete information regarding the "Sirocco" A B C Vertical Unit. Let us refer you to plants in your locality where these engines are giving reliable service.

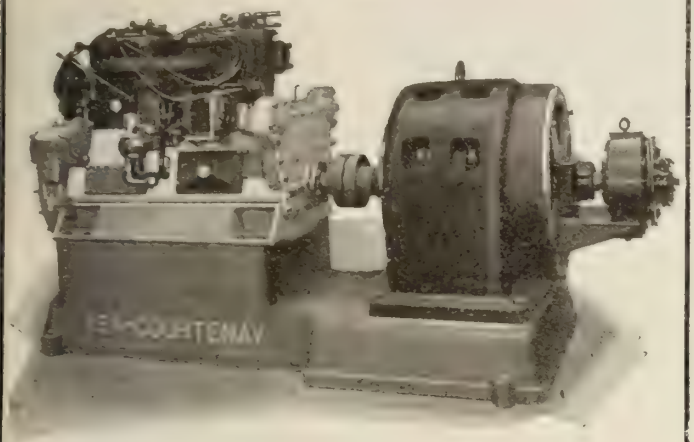
Buying Power?

What does it cost you when you run over your minimum power rate?



Model FC—4 cylinder, 80 H.P., 1,200 R.P.M. Sterling, set made up by Lea Courtenay Co., Newark, N.J., with Burke generator, for emergency in isolated district.

A Sterling high duty 1,200 R.P.M. gasoline engine costs about $20 per H.P. to buy and about the same as steam to run.

ELESCO

SUPERHEATERS
(Made in Canada)

are adaptable to new or existing boilers of any type and are applied without change in design or construction.

Meet the Overload by Equipping your Boilers with Elesco Superheaters

Forcing a saturated plant to meet an overload is expensive and wasteful. Maintenance costs mount with every strain on your boilers.

Equip your boilers with Elesco Superheaters and you can meet an overload of 200 per cent, even 300 per cent, economically, safely.

At a nominal installation cost, Elesco Superheaters add 25 per cent. to existing boiler capacity. They give you that much more power on the same fuel, or your present power on 10 to 20 per cent. less fuel.

How many capacity increasing factors do you know of that return their cost in fuel savings?

Without the slightest obligation on your part, our engineers will make a thorough study of your plant and its demands, and submit a comprehensive report covering the cost of the recommended installation, the additional capacity it will give, and the fuel savings it will effect.

THE SUPERHEATER COMPANY, LIMITED

Transportation Building, Montreal
Works at Sherbrooke, Que.

B. C. Representatives: The Taylor Engineering Company, Limited, Vancouver

Designing Engineers and Manufacturers of ELESCO Steam Superheaters and Pipe Coils for all purposes. Feed Water Heating Equipment for Locomotive Service. Boiler Feed Pumps for all Services.

The Superheater Company, Limited,
Transportation Building, Montreal.

An Expense that is a Saving

The practical engineer often realizes that poor Belts cause such a loss of time in making repairs and cause such a loss of efficiency in transmission of power, that it would be money in pocket to

BUY NEW BELTS

Good Belts Save Power and Save Money

The most correctly devised Belts, that have made records for durability and efficiency, are—"P. M. S" Belts

Used in some of the largest Mills and Factories in the Dominion of Canada. Manufactured exclusively by

Gutta Percha & Rubber, Limited

Head Offices and Factory, Toronto

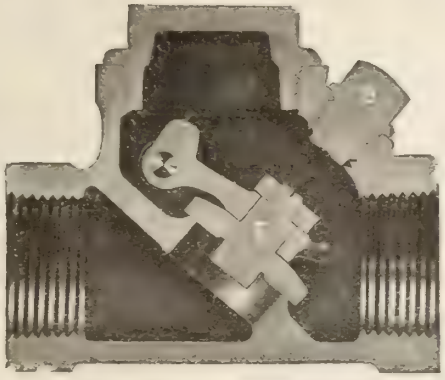
TRADE PENBERTHY MARK.

BE SURE THIS NAME IS ON THE VALVE YOU BUY



Cut No. 544-A

SWING CHECK VALVE

Get Away From Check Valve Troubles

by installing

The Penberthy Double Plug Check Valve

on Your Steam Lines

Cut No. 544A shows sectional side view and illustrates to advantage the liberal thickness of metal in diaphragm. (See letter D), also the even distribution of metal throughout. The disc (letter E) is also of liberal thickness, and as same is made of a special wear resistant bronze composition the Penberthy Check is practically indestructible, and will give many years of efficient service. All genuine Penberthy Checks bear our trade mark and the registered pressure 200 lbs., is also cast on each.

The double plug construction makes it possible to take the valve apart if mounted on a wall pipe without disconnecting same from the pipe. The plugs also act as bearings for the disc carrier pin and in case of wear it is only necessary to renew either plugs or pin, making valve as good as new. The top plug "B" is also removable for insertion of screw driver when regrinding disc and seat is necessary.

Stocked by leading jobbers everywhere.

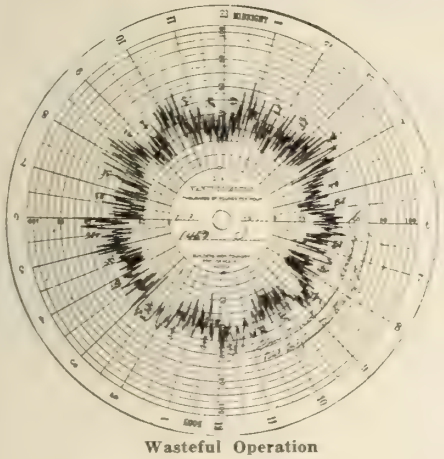
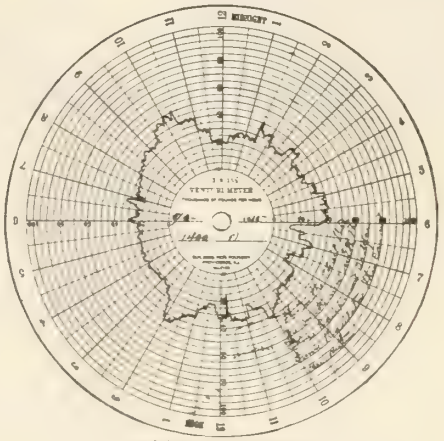
The Venturi Meter Will Analyze

The Operation of Your Boilers



Wasteful Operation

Venturi Instrument



Efficient Operation

Your boiler plant was expensive to install and is expensive to operate. The Chief Engineer must have information covering every hour of every day as to its operation, if he is to secure and maintain efficient results.
Venturi Meters for Boiler Feed Water and for Steam will provide an analysis of boiler operation from which the Chief Engineer can locate inefficient results immediately. The charts tell the complete story of the period they cover and form valuable records for future reference. Over 20 years of service has proved the Venturi supreme for boiler feed measurement. It is accurate, durable and needs little attention. It gives the momentary rate on a large dial for the guidance of the water-tender or fireman, the total flow and a 24-hour chart record 12 inches in diameter for the Chief Engineer. The Venturi has long been accepted as the standard meter for the boiler plant.

Shall we send you descriptive Bulletins?

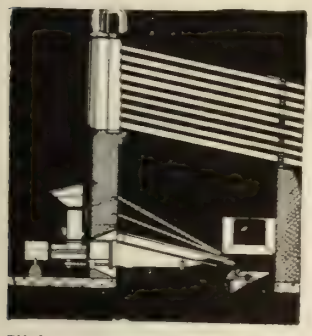
WATER

PURIFICATION SYSTEMS
SOFTENING & FILTRATION
FOR BOILER FEED AND
ALL INDUSTRIAL USES

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

Instead of a crankshaft and a lot of complications, simple self-contained retorts.



Slight slope of Jones "A-C" retort compared with gravity feed retorts (indicated by dotted lines). Instead of gravity fuel movement, positive movement.

Simplicity— without a single sacrifice

Jones "A-C" high side tuyeres (above) compared with ordinary type (below). Increase furnace width; keep fire and clinker away from side wall.

The simple balanced dump plate easily operated by one man.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co. of America are made available for Canadian power users. Thus, this strictly Canadian stoker is backed by world-wide experience and unequalled engineering ability.

Can you think of any piece of power plant equipment that is taxed as heavily and irregularly as the stoker? You can't expect a complicated, delicately adjusted device to withstand this hard grind—it's like expecting results from a race horse hitched to a plow.

The illustrations here show how the stamina of the plow horse is built into the Jones "A-C" without sacrificing the get-away and speed of the race horse. Or, to put it another way, how quick pick-up and overload capacity are combined with that sterling quality, rugged simplicity, that insures **staying power**. Consider the following exclusive Jones advantages: Instead of a crankshaft with its connecting rods, shearing pins, gears, sprockets, chains, etc., a simple steam-driven retort with one sturdy moving unit—no moving parts in the fire.

Instead of an erratic gravity feed, a positive mechanical fuel movement. Note the slight slope of the "A-C" retort diagrammed above.

Instead of side wall clinker troubles, high air cooled side tuyeres that prevent clinker formations and increase grate area.

Instead of a "high strung" complicated power dump, a rugged dumping mechanism easily operated by one man.

These features merely brush the surface of Jones betterments clearly explained in the "A-C" catalog. Ask for a copy of the new edition.

For Every Service

JENKINS' Valves are made in types and sizes to meet every requirement of power plant, plumbing and heating service.

Because of their excellent design and superior workmanship they withstand the little extra strains to which valves are frequently subjected and which destroys the efficiency of inferior valves.

Jenkins' Valves are made of selected brass, iron or cast steel and are well-proportioned throughout—the metal being evenly distributed. The fact that each and every "JENKINS'" is subjected to an exacting service test before leaving the factory is a guarantee of trouble-free service even under unusually severe conditions.

Catalog No. 8 describes the Jenkins line in detail. Write for free copy.

Carry High Overratings on Natural Draft

Boiler ratings as high as 200% can be carried with poor quality, high ash and badly clinkering coals, on natural draft, when the boilers are equipped with

FILES HAND STOKERS

They insure clean fires all the time, without necessitating slicing, poking through open fire doors. Moving a few convenient levers mounted on the boiler fronts sifts the ashes, cleans the fire, breaks up all clinker and dumps the refuse into the pit. The labor saving is nearly as great as the coal saving.
The illustration shows a typical Files installation. Files stokers are also furnished with mechanical feed where plant is equipped for it.
Write for full particulars on the Files now.

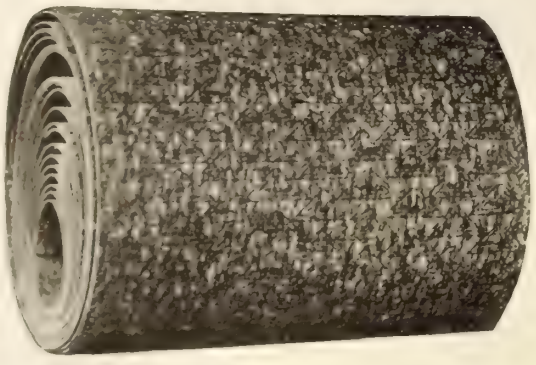
Durabla Gaskets Make Tight Joints

Extreme tests prove that Durabla Gaskets can withstand all Temperatures and Pressures without showing signs of Distress.



Wherever a permanent Gasket is required use Durabla. Durabla Compressed Asbestos Fibre Gasket Material makes tight joints on Steam, Water, Air, Oil, Ammonia and Acids. It will not burn out, blow out or pulp at the joints. Durabla is made in convenient size sheets that can be rolled and unrolled. Stamped with the Durabla trade-mark which guarantees strength, goodness and quality.

The M E. reports to the W.M.

It's a real pleasure for the Mechanical Engineer to go over his report with the Works Manager when everything is running like clock-work, due to Imperial Lubrication.

Out-put shows a good increase. Operating costs are lower than ever before. Repair expense and depreciation percentages have fallen off. And most surprising of all is the fact that lubrication costs have actually been reduced

Hundreds of plants, using Imperial Lubricants exclusively, testify to savings up to 35%. It will pay you to call in an Imperial Engineer to prescribe for your plant. Write to 56 Church St., Toronto.

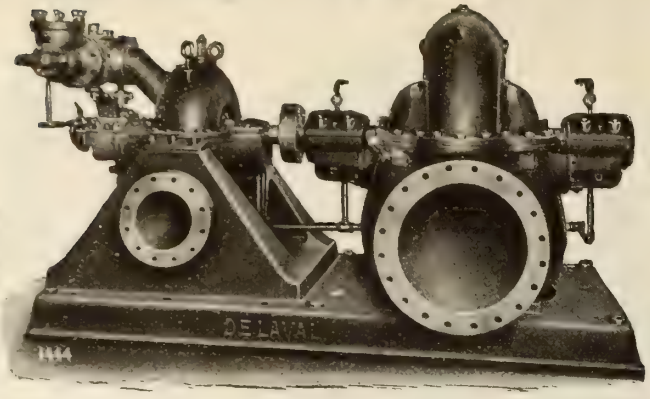
STAMINA



De Laval velocity stage turbine driving blower; 18,000 cu. ft. per min. against 40 in. water column. 3,600 r.p.m.

THIS DE LAVAL CENTRIFUGAL BLOWER driven by a directly connected steam turbine can be depended upon. It is simple and substantial. The blower casing castings are extremely heavy and the impeller and shaft are made of alloy steel. Large bearings and a pressure-oiling system insure reliable lubrication. The turbine is similarly simple and rugged. All working parts of either machine are accessible upon lifting the casing covers. The turbine is controlled by a simple and effective governor and valve gear. Hand-operated nozzles are provided to secure maximum efficiency at different loads.

De Laval blowers are built for all capacities and for all pressures up to 125 lb. per sq. in. De Laval turbines are used for driving all kinds of machinery at all speeds. State nature of your service and suitable literature will be sent.

LUNKENHEIMER
"Ferrenewo" Valves

Globe Valve, Fig. 1021
Angle Valve, Fig. 1022
Cross Valve, Fig. 1023

"FERRENEWO" Valves are *economy* valves, proved so by their record of years in service. Low initial cost, wear resisting materials and the ease of renewal of all the parts should necessity require, makes them highly desirable for piping equipment where the pressure does not exceed 150 pounds.

LUNKENHEIMER "Valve-iron" from which "FERRENEWO" Valve bodies are made is an especially alloyed and processed Ferrous Composition. The renewable *seatring* and *disc* are made of LUNKENHEIMER "Valve-nickel," while the bonnet, stem and bonnet ring are made of bronze compositions formulated especially for the duty each part performs.

The "FERRENEWO" material combination and unique design, coupled with the LUNKENHEIMER method of manufacture insures successful results under the wide range of operating conditions for which "FERRENEWO" Valves are adapted.

LUNKENHEIMER Distributors situated in every commercial center carry "FERRENEWO" Valves in stock for immediate delivery.

To standardize on "FERRENEWO" Valves is to *economize* in valve cost and maintenance.

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

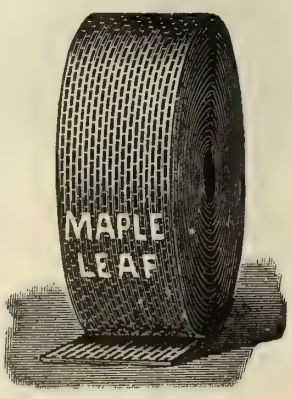
Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.



"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

Fisher Reducing Valve
11-A Expanded Outlet

Economical Heating

Economical heating is obtained only when steam is dry and hot, and when no more than necessary is sent through the system.

Fisher Reducing Valve

regulates your steam and delivers to the steam lines only the exact amount necessary to proper maintenance of a predetermined degree of heat.

It will do this automatically—without attention on your part.

The Ingersoll Packing Company, of Ingersoll, Ontario, tell of the long life of Fisher Reducing Valves:

> "We wish to say that the Fisher Reducing Valve we purchased from you in 1904 has been in daily operation since we purchased it and the results we have received have been most satisfactory."

Fisher Steam Trap

will keep your pipe lines absolutely free of condensation. It gives the steam a clear track. There is no leakage in this trap. A perfect water seal is maintained at all times. Because of its extra-large bucket it will operate more forcibly — less frequently. It handles a larger volume of condensation.

Each Fisher Specialty is thoroughly inspected and tested under actual working conditions. This gives positive assurance that they are satisfactory in every way. Fisher Specialties can be ordered from your own jobber—anywhere in Canada.

Little Belts, Big Belts and Biggest Belts

Each must do its part in turning the wheels of Industry. Little Belts sometimes drive wheels of vast importance and even Little Belts must be just right to give efficiency; big Belts and Biggest Belts in proportion. We supply some of the Biggest Belts in the Dominion to some of the Biggest Plants in the Dominion.

For DURABILITY and EFFICIENCY Use

P&H FLANGED PIPE JOINTS

SCREWED

P.H. LAP

P&H LAP FLANGES, for any service, have proven to be the best yet designed, and they have many advantages over other styles. The pipe is not weakened by cutting into the wall as when using screwed flanges. The gasket bears on the face of the lap and absolutely prevents leakage through the bore of the flange. The hub of the flange is bored slightly larger than the outside diameter of the pipe so that the flange will swivel readily and accommodate itself to any slight variation in the position of the bolt holes, an advantage which is obvious to the fitter and eliminates torsional strains in attaching.

25% More Circulation
—*No Increase in Rates!*

BY UNDERTAKING to fill, for their unexpired terms, all paid-up subscriptions to FARMERS' MAGAZINE—which ceased publication with its issue of February 2nd—MACLEAN'S MAGAZINE has thus added to its list at one stroke, approximately 20,000 paid-in-advance subscribers.

Through the general use of the automobile, the farmer has become to-day practically a suburbanite. Canadian farmers of the class who have been subscribing to FARMERS' MAGAZINE are in a position to buy automobiles, pianos, phonographs, and all other articles or conveniences that make for comfort and a higher standard of living.

Besides being consumers of the best grades of merchandise, they are to-day taking the keenest interest in politics and all public and economic questions.

FARMERS' MAGAZINE and MACLEAN'S MAGAZINE have been the outstanding mediums in Canada, serving separately the rural and urban fields. The decision to discontinue FARMERS' MAGAZINE and to fill the subscriptions with MACLEAN'S, is the result of the maturity of a conviction that the subscribers to our farm magazine are ready now to demand and appreciate a general national magazine like MACLEAN'S in order to have the information and entertainment which they desire — a magazine that will furnish them with good fiction, political articles and Canadian national news of a character not found in the farm papers or newspapers. No change is being made in the physical make-up of MACLEAN'S MAGAZINE, or in the character of its editorial contents.

95,000 Gross Circulation
Rate Based on 70,000 A.B.C.

The addition of FARMERS' MAGAZINE subscription list to MACLEAN'S circulation, after all arrears and duplications are eliminated, commencing with February 15th issue, gives MACLEAN'S MAGAZINE at once a total circulation of more than Ninety-Five Thousand copies each issue.
This gives a big general covering of town and city circulation, plus a highly selected farm circulation. It provides the tremendous influence of the "leadership" families in every city, town and village right across the Dominion, together with the most prosperous and progressive farmers in each trading territory; and constitutes a service which is not equalled or even approximated by any other general publication in Canada.

95,000 National magazine circulation in Canada, on a per capita basis, is equal to at least 1,500,000 in the United States.

**MACLEAN'S is the outstanding,
big, covering medium in Canada.**

The MACLEAN Stoker

TRADE MARK REGISTERED

Will start right in to save you money from the day it is installed!

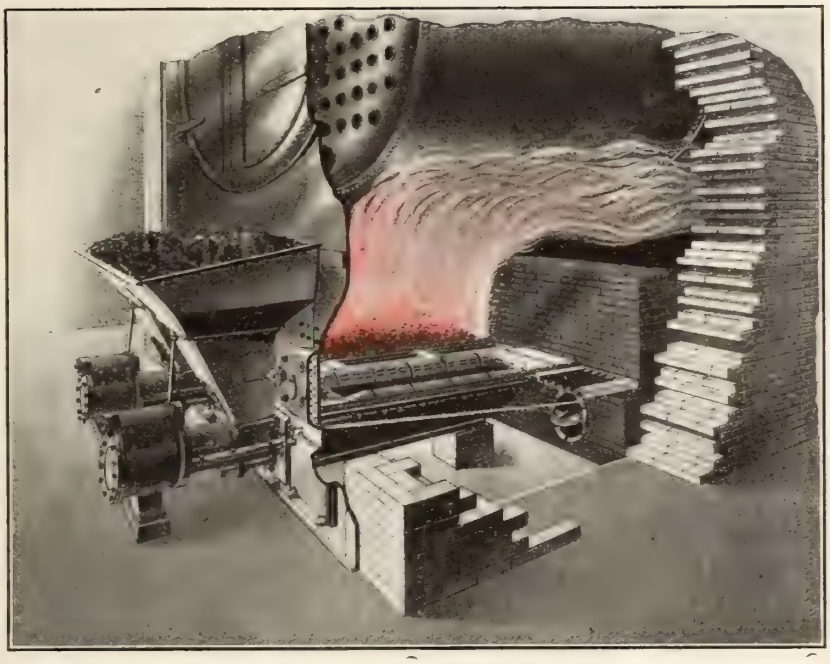
It immediately takes care of one of the biggest problems confronting the plant engineer, viz., **production of steam at lowest cost.**

The MacLean Stoker is adaptable to practically every type of boiler and to all classes of steam plants. Canning Factories, Rubber and Tire Plants, Pulp and Paper Mills, Laundries, Tanneries, Woollen Mills, Dye Houses, Public Institutions and Office Buildings are typical installations where large reductions in the coal bills are a sure result.

There are many reasons why your next stoker should be a MACLEAN. It has the construction that is dependable and essential to boiler plant equipment.

Look over the features stated and write us for fuller details.

MACLEAN UNDERFEED STOKER CO.
LIMITED
95-97 King Street E. TORONTO



A constant uniform steam pressure is carried regardless of varying loads on the boilers.

A smokeless chimney is maintained. Will not infringe the smoke by-laws of any city—anywhere!

Coal consumption is reduced.

Responds automatically to sudden demands for steam.

No siftings of unburned coal to the ash pit because there are no grates.

The steaming capacity of the boilers is increased.

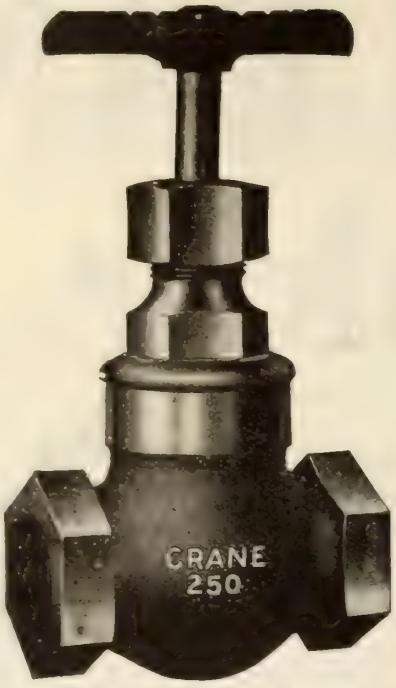
Cleaner Tubes and heating surfaces due to clear combustion.

Small cost of upkeep on account of the simple construction. There is **not one** moving part in contact with the fire.

No special brickwork is needed.

Easy to install, easy to operate—No previous knowledge of stokers is required.

Soon Pays the Cost of Installation



No. 60 E

CRANE

Extra Heavy GLOBE and ANGLE VALVE with Copper Disc

The Crane Copper Disc successfully overcomes the many objections found in some types of hard rubber or composition discs. The construction of the disc and holder is such that the disc may be easily taken out and replaced.

Which Stoker?

—You Make this Decision Once—It Must be Right

EXPERIMENT with any equipment is costly—but experiment with mechanical stokers is out of the question. The investment is large; it is made once in a lifetime; snap judgment won't do—*which stoker?*

Canadian plants want greater boiler capacity—continuous power day and night when necessary—they want this accompanied by greater economy in burning Canadian coals and by lower labor costs.

This means *high-duty stoker firing,* best exemplified by the Jones "A-C" (Automatic-Cleaning) Stoker.

Regardless of the size of the plant, the grade of coal burned or the local conditions to be met, the logical, safe answer to *"which stoker?"* is Jones "A-C."

The new "A-C" catalog goes into detail. Jones engineers with unmatched experience in this specialized field, will gladly make a survey of your plant and give you the full benefit of the best they have learned in installing stokers in many prominent power houses. Investigation implies no obligation.

The Canadian Stoker
Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co., of America are made available for Canadian power users. Thus, this strictly Canadian stoker is backed by world-wide experience and unequalled engineering ability.

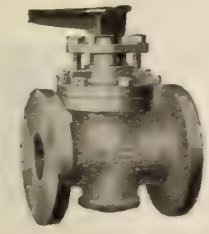
HOMESTEAD

Quarter-Turn Valves

Economy!

A valve to be economical must give dependable, lasting service.

Homesteads open and close easily. The patent balancing parts insure it against sticking. When the Homestead is fully opened, the two surfaces which are depended upon for tightness are in no way affected by the material passing through. The plug cock provides a straight-way opening which is desirable in all sorts of work but particularly so in high pressure service—also in the handling of thick heavy liquids.



Elimination of waste time and leakages quickly pays for all Homestead valves. You would do well to adopt them without delay.

The Jennings Hytor Vacuum Heating Pump

THE ADVANTAGES of vacuum in connection with steam heating are well understood, but in installing equipment consideration should be given economy, efficiency, and durability. In these respects the **Jennings Hytor Vacuum Heating Pump** deserves careful attention. It is distinctly in advance in principles of design compared with other types; principles of design which assure reliability, perfect service and low up keep cost. Another feature is compactness, and the horsepower required for its operation is less than half that consumed by other vacuum heating pumps of similar capacity. **Study the illustration, then write for catalog.**

The Power Plant of the King Edward Hotel

Our Readers Are Taken Down Into The Basement and The Inner Workings of the Power Plant and All Its Contingent Apparatus Laid Open For Their Inspection

By T. H. FENNER

By permission of Mr. G. H. O'Neil, General Manager, United Hotels, Ltd.

THE CITY of Toronto has a habit of being proud of its features, and of itself as a whole. When hotels are mentioned in Toronto the King Edward is naturally though of as being the biggest thing of its line in the city, and its new eighteen-story building is a prominent feature of the landscape, or rather skyscape, for visitors entering Toronto by boat.

A hotel like this, which contains within its walls between guests and staff, enough people to make a little country town, has to be able to attend to their needs and fancies in a pretty wholesale way, and its services must never be allowed to slack off, on any excuse whatever. It must be lighted, heated, ventilated, and cooled, every minute of every hour of every day in the year.

A factory can be closed down at night, and at week ends, and any needed repairs or alterations carried out with some reasonable allowance of time. A hotel can never close down for a minute. The demand therefore on the machinery and staff that are responsible for its upkeep, is a never ceasing one.

Day in and day out, year to year, the ever-ready current must be on the wire to flash into light when the impatient guest turns a switch, the water must be hot in the tap when he turns on his bath, the ice must be ready to cool off his drinking water, the elevator must be running to take him upstairs or down.

In addition to these things which are apparent to the sight and touch, there are many others which are necessary to his comfort, but with which he never comes in contact. His room is cleaned and swept by the same willing current which lights his lamp, and operates his telephone. His food is kept fresh and sweet in refrigerated store rooms, ice cream is frozen by brine from the same refrigerating machines, and the ice for his ice water is another product of the plant. There are the freight elevators which bring up his baggage, the existence of which he is probably not aware, but they also are driven by the current which comes from the lowest depths of the building. The guest takes all these things as a matter of course, and it is safe to say that perhaps not one half of one per cent. of them ever give a single thought to the means by which all these things are provided to their hand.

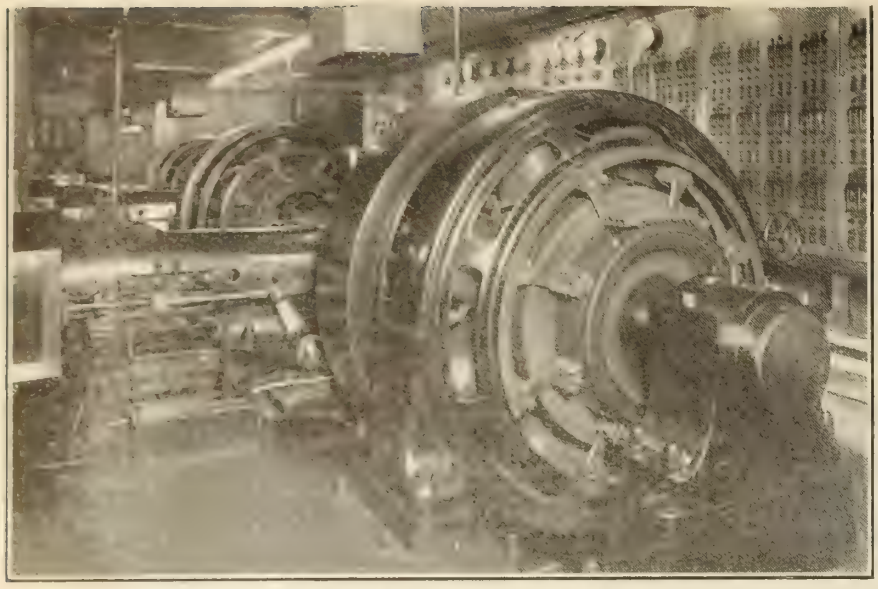
The Hidden Power

Down below the level of the street, part of it even forty-five feet below, is the plant which daily performs these miracles. One could be in the kitchen next door to it and not know of its existence for there is neither sound nor smell to tell that there are engines producing power and light, and refrigerating machines making ice, and boilers generating steam to supply power and heat, just through an ordinary door. The thing that cannot help striking the observer, is that this same note of quiet efficiency pervades the whole plant. No one seems to hurry, no one raises his voice, and the work goes on with a great deal less fuss than can often be seen in the boiler room of a one-horse saw mill.

It can readily be understood, that the provision of an entirely new building, with all these services to be installed, the while all the functions of the old building went on undisturbed, was somewhat of a problem. However, by ample foresight, and careful preparation for every move, the entire new installation was installed and connected up without anyone outside of the power plant knowing it was going on. No guest suffered a moment's inconvenience, and the fact that the new building was just about ready by the time the heating season came on made it all the more important that the system should be ready to function immediately it was called on. It was able to fulfill this condition, through the efforts of all concerned, contractors and staff alike.

The original plant of the hotel, which is operating to-day, consists of three Babcock & Wilcox watertube boilers,

The original switchboard. The new interconnecting board is at the far end.



One of the main generators.

of 250 h. p. (rated) each. These boilers supplied steam to the engine room, the kitchen, and heating system, and to some extent are doing the same thing at present. Eventually these boilers will be discontinued, when the new plant is completely installed, but just now they are doing business as required.

In the old boiler room are the original vacuum pumps and boiler feed pumps, and the original Webster heater, supplied by Darling Bros. The vacuum pumps are of the Burnham type, made by Darling Bros., and are two in number. One of them is 10 x 4 x 16, the smaller one being 8 x 10 x 12. These pumps are so arranged that either of them can operate on the heating system alone, while the other handles the kitchens and laundries, or they can either of them handle the whole thing.

The main steam header from the boilers is arranged to supply the engines and refrigerating machinery, and can also supply the heating services. In addition to this there is a 4 inch auxiliary line, which is also connected, as a loop leaving the main header free for any necessary repairs.

The old boiler plant is now connected up with the new one, but we will refer to this phase later.

The boilers are fed by two Burnham, outside packed, horizontal feed pumps, drawing their water from the Webster open feed heater.

We had the pleasure of looking in the top drum of one of these boilers, which was down for cleaning, and we can safely say that never have we seen a boiler in better condition after eighteen years of service. The plates were smooth and showing just a suspicion of shine, due to the judicious use of graphite. [illegible] after such long service as it must using exhaust steam for [illegible]. Mr. Pike is very proud of his boilers, and has good cause to be.

Proceeding from the boiler room, we extends across the front of the building. The photographs here reproduced will give a good idea of the layout. The units in detail are as follows. No. 1 generator, 225 volts, 200 amps, 270 r. p.m. direct connected to Robb Armstrong horizontal engine.

No. 2 generator, 225 volts, 400 amps, 260 r.p.m. direct connected to Robb Armstrong engine.

Nos. 3 and 4 generators, 225 volts, 625 amps, direct connected to Robb Armstrong horizontal engines.

Two motor generator sets transforming two wire to three wire distribution.

Two Linde British 30 ton ammonia compressors, direct driven by Wheelock steam engines, providing cold storage and icemaking for the entire hotel. About 4 tons of ice is made per day in addition to the cooling of store rooms and making of ice cream.

The generators mentioned above supply current to the main switchboard from whence it is distributed to the various circuits throughout the building. There is also a connection from the wires of the Toronto and Niagara Power Co., coming in on the same board, so that the services of the hotel can be supplied either by their own plant or the outside power.

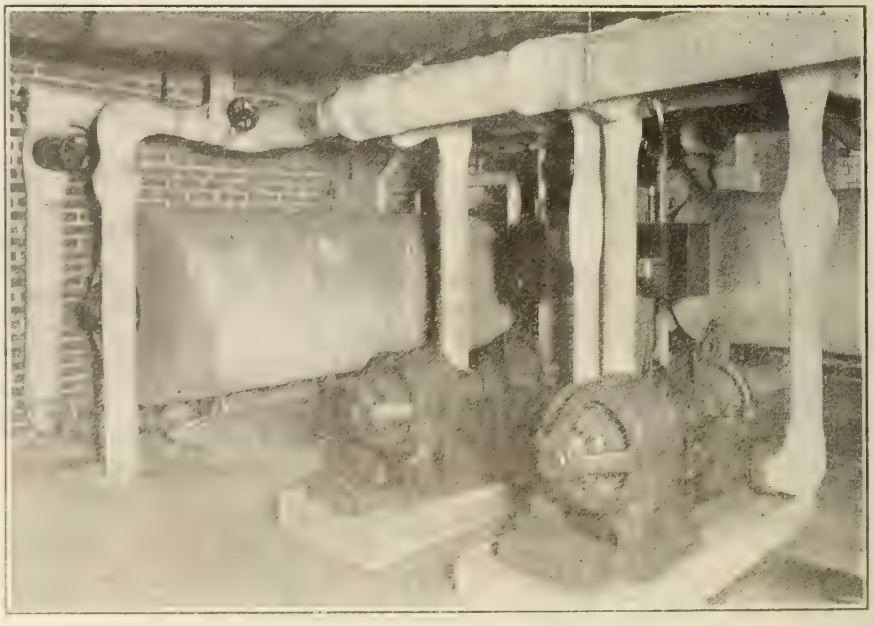
In connection with the necessary current for the new building, and the tying in of the hotel plant and the outside power to procure the necessary flexibility, a large amount of work was entailed. This included installing a new underground service from the T. N. P. Co.'s station at Scott Street, to a manhole on Colborne, near Victoria Street, from which the wires are taken into the hotel basement, and connection made to a two-pole switchboard. This switchboard is of slate, two inches thick, and contains two panels.

The cables carrying the supply from Scott Street consist of three 1,000,000, C. M. lead-covered cables parallel to each leg. The No. 1 panel of the board mentioned above carries a 1,500-Ampere 260-Volt 3-pole D. C. industrial type Roller Smith circuit breaker for light and one 2,000 Amp. 250 Volt D. C. circuit breaker for power, same type.

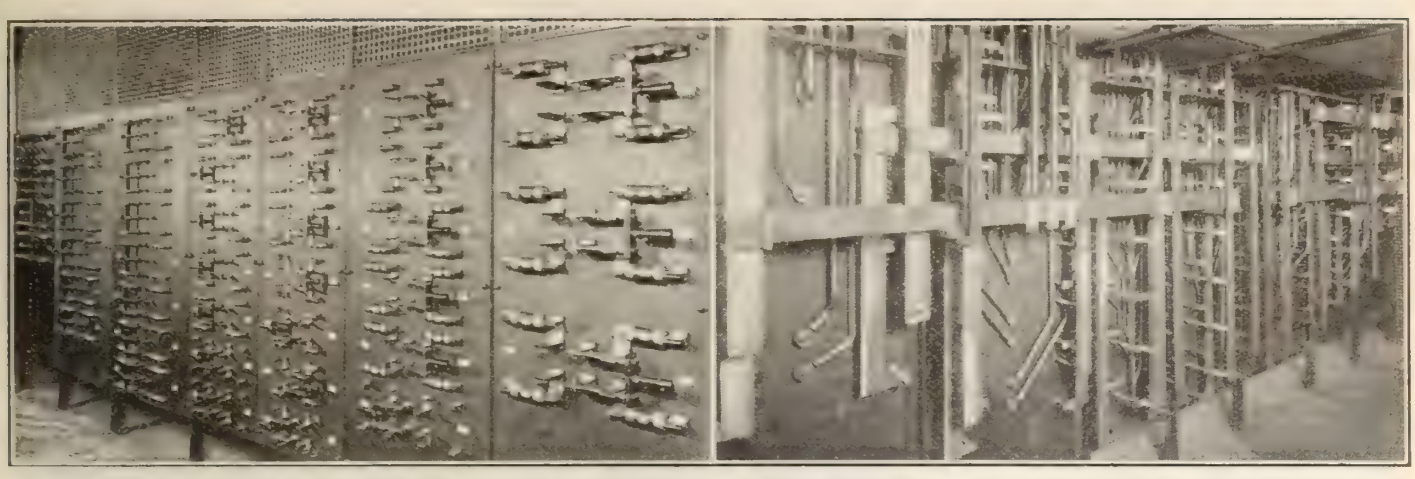
The second panel contains the necessary power and light meters for the services of the T. N. P. Co., including a graphic meter with the necessary shunts. From this board the necessary cables are carried over to the distribution board in the engine room. This switchboard carries one 1,000 Ampere, 250-Volt 3-pole circuit breaker for the new switch board, one 300 Ampere 3-pole 250-Volt breaker for the old switchboard, and also one 600 Ampere 3-pole 250-Volt breaker which ties in the present generator switchboard panels to the new distribution board.

On a second panel of this same board are carried the three corresponding power circuit breakers.

This switchboard, then, affords a



[illegible] hot water heaters, and motor driven centrifugal house service pumps, installed by Darling Bros.



Front and Back View of New Distributing Switchboard For New Build ng. Board Made By Drive Switch Co., Under Instruction of Ramsden and Roxburgh, and Otto Goldschmidt (Consulting Engineer.)

means of putting the T. N. P. Co. current onto the old switchboard, and the new switchboard at the east end of the engine room. It also allows the current from the generators to be put on to the new switchboard, and allows a means of balancing the load from the hotel's own generators and the outside current in any proportion required by the operating staff. It also precludes any possibility of a failure of current, as there is always the alternative of the T. N. P. Co. power and the hotel's own. As the hotel has four generators, the possibility of a complete failure of current is so remote as to be outside the bounds of probability.

The distributing board just mentioned was made by the Benjamin Electric Co., to the design of Messrs. Ramsden & Roxburgh, the general contractors for all the electric work necessary.

The new switchboard for supplying the new building which is shown in our illustration, both a front and back view being given, was supplied by the Devoe Electric Co. of Montreal, to the design of Messrs. Ramsden & Roxburgh. It contains 7 panels, and is arranged with double throw switches for either hotel power or T. N. P. Co. power.

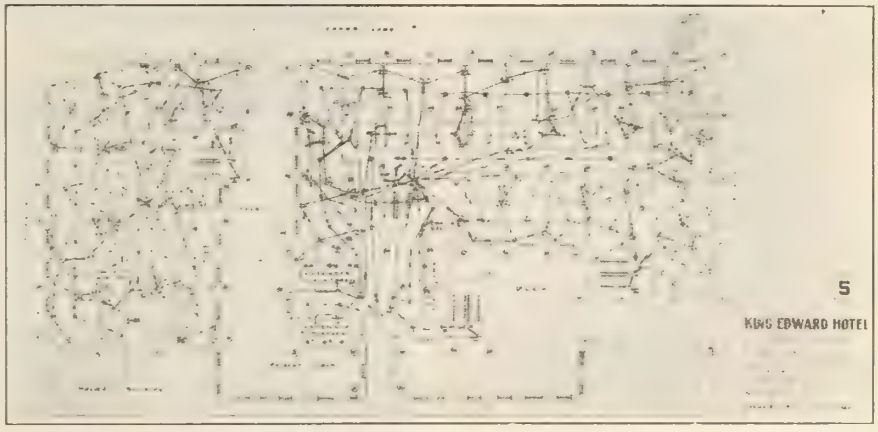
A new type of construction has been adopted for the connections between the switches and cable box. Instead of following the usual practice of connecting the cables directly into the switches, the cables terminate in a box above the switchboard, which runs the whole length of the board. Connection is made between the cables and the switches by means of copper connecting rods. This enables a much neater general finish to the back of the board, as the connecting rods are all uniform. It also allows of an easy means of increasing the section of the connections if required at any time.

The photograph reproduced gives a very good idea of the general appearance of the back of this board.

Just above where the connecting rods terminate, and on the bottom side of the cable box there is a slate slab which serves the purpose of holding the connecting rods in place and also provides a split lug for the cables. There is a bronze grille which can be seen in our illustration entirely surrounding this cable box. In the building itself there are five panel boards for power distribution and 53 panels for lighting. These panels vary in size from 4-circuit to 32-circuit. They were constructed to the instruction of the consulting engineer, Otto E. Goldschmidt, of New York, by the Devoe Electric Switch Co.

Some idea of the size of this job may be gathered from the fact that 120,000 feet of conduit and 315,000 feet of wire were used. No less than 20,000 locknuts and bushings, while receptacles and outlets of various types amounted to 35,000.

The total connected load is in the neighborhood of 650 h.p. divided between the two buildings as follows: in



Plan of wiring arrangement for lighting system on one floor of new building.

he new building there is 300 k.w. lighting and 375 k.w. power load, and in the old building, 200 k.w. lighting and 115 k.w. power.

An idea of the lighting distribution can be gathered from the reproduction of the wiring plan shown here.

House Service Water

At the east end of the engine room, after passing the ammonia condensers and the new distributing board for the new building, one reaches the hot water heaters and also the house service pumps.

It is necessary in a building of this height to provide other means than the ordinary city water pressure to supply the upper floors, otherwise they would go without. The height from the engine room basement to the gallery where the water tanks are situated is approximately 220 feet, and as this corresponds to a pressure of 95.48 lbs., it can be understood that it is beyond the reach of the ordinary city water works pressure.

In order to insure a constant supply of water to the rooms, two house service pumps are fitted in the basement which are controlled automatically by the water level in the tanks on the roof. These pumps are of the type known as Darling Class B, centrifugal, direct connected to motors. The illustration shows the arrangement plainly. These pumps are designed to deliver not less than 200 gallons per minute each under the conditions prevailing, which are, of course, a suction pressure corresponding to the pressure in the city mains, and the discharge due to the head water. The float controls are so arranged that the higher float will first start one pump, and then if the water still drops, a second float will start the second pump. As the water gains the pumps

will be cut out in the reverse manner the lower float cutting out the second pump started, and the upper one cutting out the first pump when the water level is regained. It may be mentioned here that the consumption is over 200,000 gallons per day. It has been observed by actual timing, that from the time the float trips the control until the water is being delivered into the tank, is exactly eleven seconds. This is pretty nearly as quick as thinking.

The hot water heaters contained in the same room as the house service pumps are also shown in the photograph. The large one is a Darling-Whitlock combined hot water heater and storage tank, 48 inches in diameter by 168 inches long, inside measurement, with a storage capacity of 1,350 gallons. The shell is of steel ⅜-in. plate, the longitudinal seam being double riveted. The heating surface is provided by 450 feet of 1¼ in. outside diameter No. 16 gauge seamless drawn brass tubing. The tubes are U shaped, and both ends are expanded into a forged steel header, which is bolted to the steam expansion chamber. The overhanging ends of the tubes are supported in such a manner as to take the strain off the neck where they are expanded into the header.

The steam connection to this header is 5 in. and a 2-in. drip is provided for the condensation. The tank is fitted with relief valve, thermometer, Power's automatic regulator, etc.

In addition there is a smaller heater for supplying the laundries and kitchens, 42 inches diameter by 120 inches long, and containing 720 gallons storage capacity. The heating surface in this heater consists of 300 feet of 1¼ brass tube No. 16 gauge, and the same fittings as the larger one.

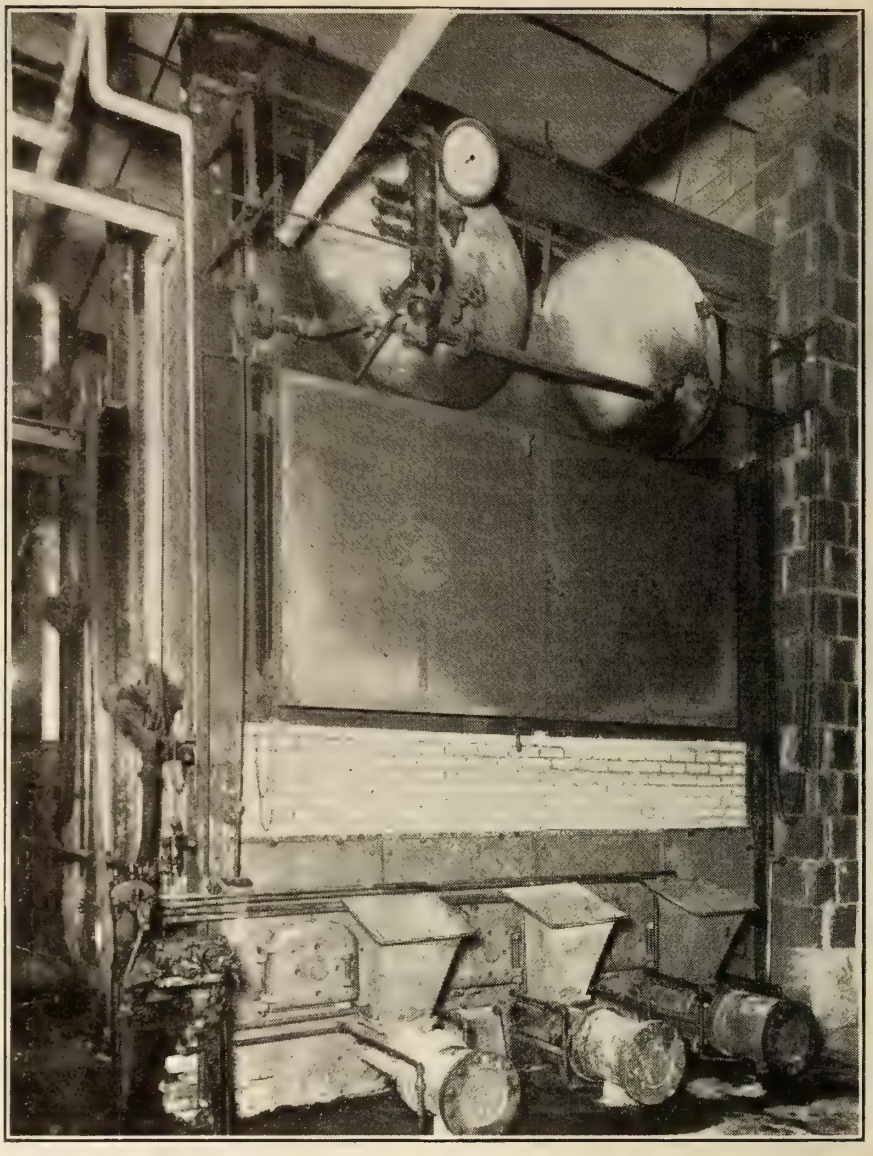
The drips are arranged to be carried either to the vacuum pumps or to the sewer, as may be required.

The New Boiler Room

Leaving the pump and heater room, we journey through a corner of a kitchen, absorbing an odor of savory soup in the process of boiling in huge copper kettles, along a corridor, round two or three more corners, meekly following our guide, until we arrive at the head of a staircase. As we are already in the basement, it looks as though there must have been some considerable excavating done when we have more stairs to go down.

This is the case, as we find. The new boiler room floor is just forty-five feet below the level of the sidewalk, and quite a long way from the engine room and the original boiler room. If the plans had been carried out as originally conceived, or as they will eventually be carried out, this isolated position would not matter, but as things are, it involved a good deal of trouble.

The new boiler room was designed to contain four boilers, and these four boilers were to take off all the load from the boiler plant, which would then be obsolete.



Front View of New 400 H. P. B. & W. Boiler, and Jones Stokers.

The new plant when complete is to consist of three 250 h.p. Babcock & Wilcox boilers and one 400 h.p. of the same type. At present the 400 h.p. is the only one installed. This is a case where the engineers propose, but the financiers dispose, and for the time being these gentlemen decreed one boiler only.

Had the original plans been carried out immediately, it would have meant that one day the new piping could have been connected to the old main steam pipe in the engine room and the old boiler room and its connections from the engine room back could have been cut off, and dismantled at leisure.

As it turned out, the two plants have had to be interconnected, so that the new 400 h.p. boiler at one end of the building is working in connection with one of the old 250 h.p. boilers at the other end of the building. The new boiler is considerably below the level of the old boiler in addition to being so far away from it. This of course involves operating difficulty, when the vacuum return system is remembered. If the operators in the new boiler room do not observe good care, they will take all the returns from the whole building, and leave the higher boiler with no hot water for feed purposes. However, the men in the new boiler room manage very nicely to check off their pump sufficiently to keep the other fellows going without any trouble.

The piping arrangement in the new boiler room, installed for the heating contractors by W. J. McGuire, Ltd., can be fairly well seen by the illustration herewith. There is one showing the main steam pipe leaving the boiler top and coming down in two very nice expansion bends to the header, which goes across the boiler room to the main riser.

From the boiler the main steam also goes across to the engine room, where it connects to the header supplying steam to the engines, and also by a branch through suitable reducing valves to the heating main. In this way steam can be supplied to the engine room or the heating system from either boiler room.

The main riser which is fitted with Vanstone expansion joints, this type of joint being used throughout, goes right

up to the sixteenth story, to a pipe gallery. Here it connects into a horizontal main on the ceiling, from which branches are dropped to each floor to supply the radiators. This overhead distribution system is used entirely in the new building.

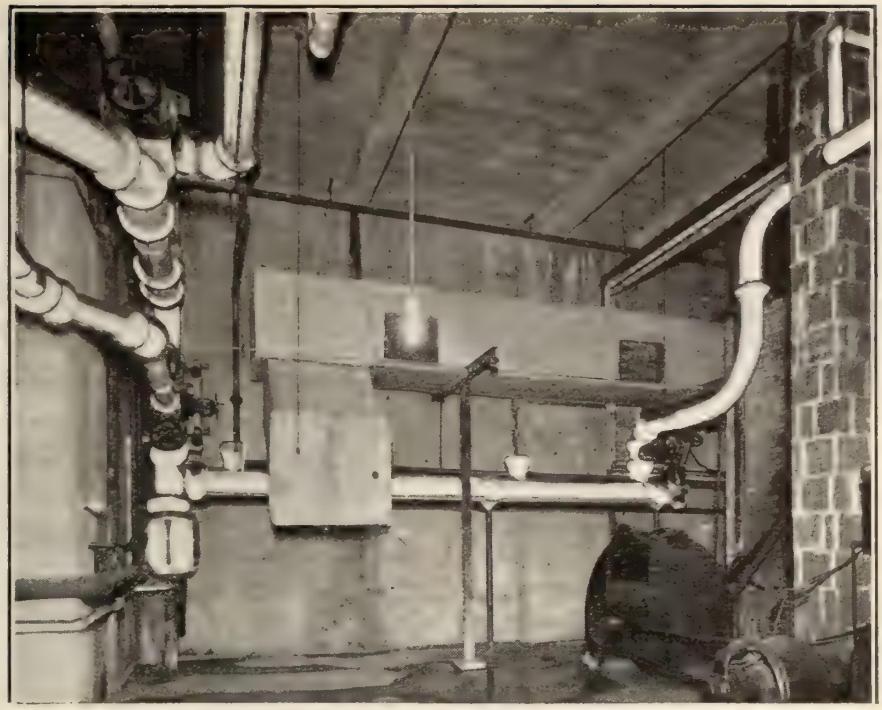
The returns from the radiators come back through risers into a four-inch main which connects with the vacuum pumps. The vacuum pumps discharge into an air eliminating tank which is situated on a gallery above the feed water heater. This tank is 36 inches diameter by 84 inches long. From the tank the water discharges through a water seal into the feed water heater, an automatic float being fitted to keep the water level constant. From the top of the tank an air pipe is led to the roof to discharge the air which is separated from the return water.

The feed water heater in the new boiler room is a Webster Class E. B. "Star Vacuum" type, to supply 1,500 h. p. It is approximately 49 inches square by 8 feet high, and is furnished with an oil separator and water softening and purifying medium. There is a 6-inch connection to the feed pump suctions, which branches off to a 5-inch to each pump suction.

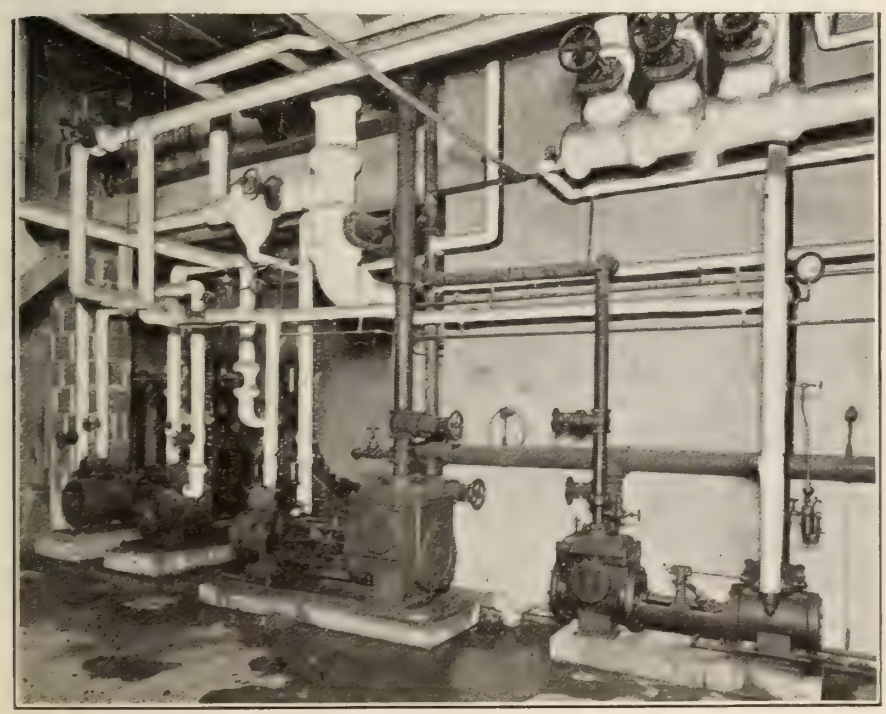
The feed pumps of which there are two, are of the outside packed type, Burnham, made by Darling Bros., Montreal. They are of the simplex type 14 inches by 9 inches by 16 inches.

There are also two vacuum pumps in this boiler room one of 10 x 14 x 16, and the other of 8 x 10 x 12. It will be noticed that these pumps are a duplicate of those in the old boiler room. It is the intention when the new plant is completely installed, to have both the large vacuum pumps in the new boiler room, but as the arrangement exists at present, each boiler room presents a completely independent unit if so required. The new boiler is fitted with a three retort standard type Jones underfeed stoker, furnished by the Underfeed Stoker Co. of Canada. There is a blower engine and fan, supplied by the Canadian Blower & Forge Co., for furnishing forced draft.

For the present coal is dumped down a chute from the street level, and fed into the stoker hopper by hand, but when the plant is complete, there will be a conveyor from the bunker to the hoppers, eliminating the hand work.



This view shows steam connection from new boiler crossing to riser and bypass.



Feed and vacuum pump. The air eliminating tank is in the corner above the feed pumps.

The pressure carried on the main steam piping (high pressure) is 125 lbs. and this is reduced where required through reducing valves to supply cookers, washers, laundry, and heating system.

The main steam header is carried over to join the present header in the engine room, and from this header are carried all the necessary connections to pumps, etc., as well as a reduced steam connection to the heating main, and a reducing bypass to the heater.

The exhaust piping and heating mains are so arranged that there is no possibility of a high pressure being developed in the low pressure lines, an atmospheric relief valve guarding against any possibility of such an occurrence.

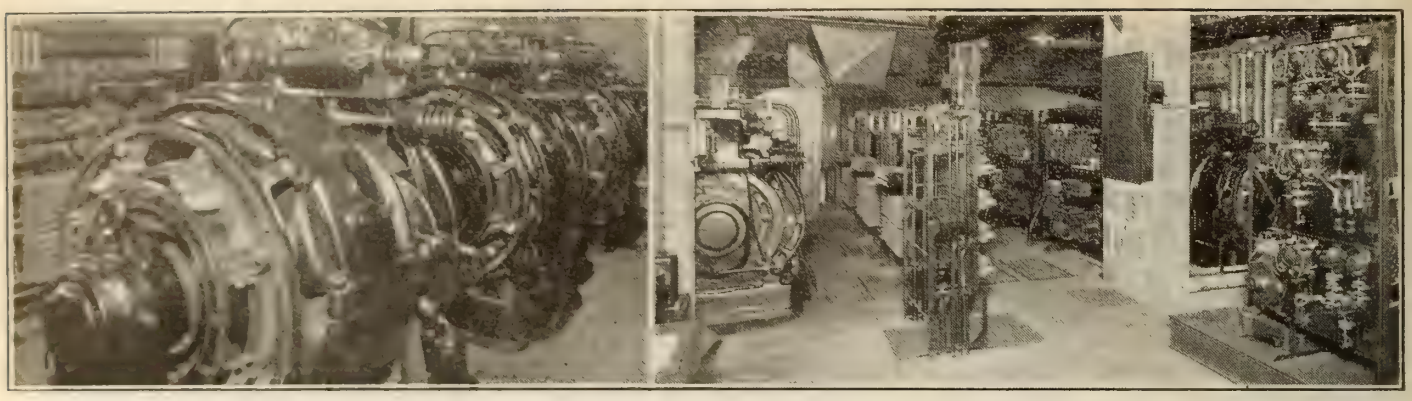
All the heating arrangements above the basement in the old building are taken care of by the main return system, but the heating apparatus on the basement level is provided with a separate line. This was found necessary some years ago before the new building was ever thought of, and considerable trouble was experienced with one section of the old building.

It was discovered that this trouble was due to what practically amounted to a water seal on the return piping, which dropped below the level of the vacuum pump, and then rose again to the pump suction, forming practically a U bend and holding up the returns from this particular point.

This bend was straightened out by the introduction of this special basement line, and the trouble was forever eliminated.

Boiler Room Drainage

Owing to the fact of the new boiler being so far below the street level, it is also below the sewer level. Provision has therefore to be made for taking



A view of the motors, and of the control gear for the six Otis Fensome Passenger Elevators.

care of the surface water which would otherwise lodge on the boiler room floor. To handle this there is fitted two No. 2 grade Duplex Yeoman's sump pump and sump.

The sump consists of a 48-inch by 48-inch by 6 feet deep brickwork well, and the pumps are two vertical centrifugal two-inch, direct connected to 240-volt direct current motors. These pumps will deliver 75 gallons a minute when discharging against a twenty foot head. They are automatically operated by floats in the sump, and a second one if the first pump cannot overcome the water. Auxiliary steam pumps for this purpose are also fitted as a standby.

Pressure on System

The heating system carries a pressure varying from atmospheric to 1 lb. per square inch on the feeding side, and the vacuum pumps maintain a vacuum of about 15 inches on the return side. This gives a total difference of pressure when the syphon traps on the radiators open of about 8 lbs. per square inch, so that there is little possibility of any holding up of the system.

It is absolutely necessary that the radiators should function without any hammering or gurgling noises and the high vacuum maintained materially assists in this result. There is an entire absence of any noises throughout the whole system, which speaks well for the general workmanship and arrangement of the installation.

Ventilating System

When the heating is taken care of there is another most important feature remaining, and that is the ample ventilation of the rooms and public assembly halls, of which there are quite a number.

This is taken care of by a number of fans, each caring for a different department. The large ballroom on the top floor requires a fan all to itself, as may be supposed, when it is remembered that there may easily be from 600 to 800 people dancing there at one time.

The fan supplying ventilation for this room is a Canadian Blower & Forge Co., No. 8 Niagara Conoidal with a capacity of 15,800 cubic feet per minute against a static head of ⅞ inch, and an outlet velocity of 1,700 feet per minute. This fan is driven from a motor by a belt drive.

There is also an exhaust fan for the ballroom with a capacity of 13,000 C. F. M. against a static head of ¾ inch, and a velocity at outlet of 1,400 cubic feet per minute. These two fans are arranged so that the direction of the air current can be diverted in the following manner. In ordinary weather, the supply fan draws in air from the louvres in the side of the building, and the exhaust fan takes the air from the room and discharges it outside.

When the weather is exceptionally cold, the dampers communicating with the outside air are closed off, and the damper between the exhaust fan duct and the supply fan duct. The air is then taken from the ballroom, passed through the air washer, with its tempering and reheating coils, and returned to the ball room at the proper temperature and humidity for the comfort of the occupants.

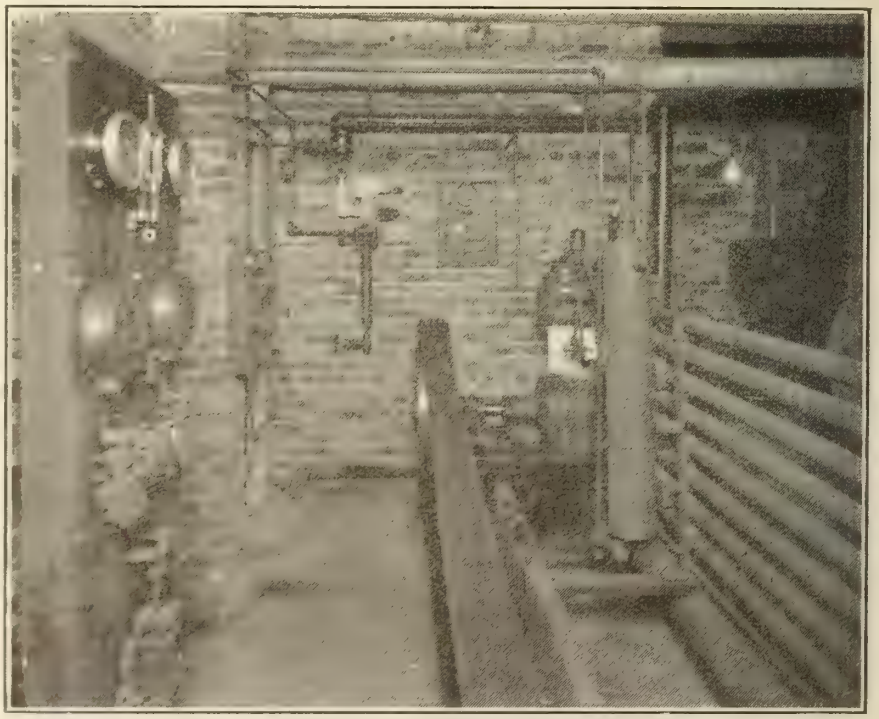
There are two fans with a combined capacity of 29,600 feet per minute for exhausting the bathrooms, and for the kitchen on the top storey there is also a fan having a capacity of 10,700 cubic feet.

There is a boiler room supply fan, with a capacity of 15,000 C. F. M., and a boiler room exhaust fan with 23,600 cubic feet capacity.

There is in addition in the engine room a Carrier air washer and fan with tempering coils for supplying air to the basement. The tempering coil and reheating coil have between them 960 square feet of heating surface, and they are guaranteed to provide absolutely pure air. This air is first relieved of all its moisture in the tempering coils, cleaned of all impurities, and then passed through the reheating coils at a definite temperature and relative humidity, which can be controlled to any desired point.

A Few Little Things

Outside of what may be considered the plant proper, there are a few little details which come under the watchful eye of the chief engineer.



York Refrigerating Machine Working Automatically for Upstairs Kitchen. Installed by the Canadian Ice Machine Co.

The engine room and maintenance crew of the King Edward. Mr. W. H. Pike, the chief engineer, is in the centre of the second row, seated.

For instance, there is a complete pneumatic system of tubes, communicating with the dining rooms, etc., and the cashier's desk, office, etc., which is operated by a fan driven by a 35 h. p, motor. A static pressure of about 2 inches water is kept on these tubes. The time required to send a message from the ground floor to the sixteenth is three seconds.

There is also a telephone system, which carries a switchboard with 1,000 stations on it, and requires 6 operators to attend to its wants. There is an ingenious system in connection with this board, for checking up messages and outside calls which have to be charged.

The operator as soon as she has finished with a call makes out a slip, which she deposits on a traveling belt running along the top of the switch board. This carries it along to a shute, down which it drops to land at the elbow of the cashier in the office. Thus no time is lost and an accurate check is kept on all messages.

This switchboard by the way is an example of the most modern equipment in existence on these lines. Among the incidentals we might include the six high-speed elevators, which do all the work of the hotel as far as the guests are concerned. There are also three freight elevators, which are out of sight of the visitor, but which are kept very busy indeed by the staff, transporting baggage, food, etc., to the upper floors. Our photograph shows the overhead work of the passenger elevation, which are the Otis, Fensome Co.'s installation. The elevator room makes a very imposing appearance. At the north end of this room is a small automatic York refrigerating machine which is solely for the use of the upstairs kitchen.

On a still higher floor are the overhead gear and motors of the freight elevators, and in this room also are contained the overhead tanks which carry the water supply which we spoke of earlier in the article.

The Engine Room Staff

To carry on all the activities of which we have given a small glimpse necessarily means a competent staff.

Mr. William Pike, the chief engineer, who has been in charge of the light, heat and power department of the hotel for the past ten years, and who has been connected with the department for the past eighteen years, is the gentleman who directs all the operations of the power department. On his shoulders has fallen all the brunt of the structural alterations, and the fitting in of this and that in such a manner that everything would go on as usual while the heart was being torn out of the building, It is Mr. Pike's pride that in all the ten years that he has been in charge, there has never been an interruption to the service, and whatever the difficulties that may turn up and have turned up, they have carried on down below without taking their troubles upstairs.

Mr. Pike's staff work mostly on the eight-hour shift principle, and no one on his staff works more than forty-eight hours per week. He has things so arranged so that he has a spare man to throw in any position should the emergency arise, recognizing the fact that one never knows the minute that these things occur. In this way there is no danger of a tie up through trying to work with an inadequate staff.

To his staff he gives no unstinted praise, and one can see that he feels a great pride in them. The details of operation he leaves to them. There is a watch engineer on every shift who is to all intents and purposes in charge of the plant while he is on duty, and this leaves Mr. Pike free to look after the broader situation which is certainly one man's job.

We have been fortunate enough, through the courtesy of the chief engineer, to obtain a photograph of the entire engine room staff, which is here reproduced, and no doubt many of our readers will recognize some old friends among them.

The group includes engineers, electricians, firemen, carpenters, bricklayers, plasterers, etc. who are employed in general maintenance work all of which comes under the jurisdiction of the chief engineer.

THE LATEST IN SCIENTIFIC VENTILATION

Very rapid strides have been made during recent years in the development of ventilation systems in Great Britain. Quite the most ingenious installation for an assembly house is that which is being arranged in the new council chamber of the London County Council. Each member is supplied with a current of pure air at the proper temperature, the speed of the current being so adjusted that no feeling of draught is experienced. The stream emerges from the desk in front of the member and drifts over his head. At his feet there is a small electric heater which can be switched on if desired. Thus the system is designed to keep the member's heads cool and their feet warm, a condition which is understood to be the exact opposite of what usually exists in representative bodies.

Another unique ventilation equipment recently installed in London is at a large film studio. The frequent occurrence of fog and the still more frequent tendency to haze in the atmosphere causes great expense and delay in the taking of film pictures in London studios. In order to ensure continuous working, an automatic system of warming and damping the atmosphere of the building was designed. All the air entering the studio is washed, filtered, and warmed; and the control is so arranged that whatever change of temperature or condition of the outside air takes place the inside air is altered in such a way that no fog is produced. The control is so delicate that even the switching on of one or two lamps in the studio meets with an immediate response by the automatic plant. An endeavor is now being made to remove from the incoming air various gases which are contained in a London fog. These gases have no effect on the photographs taken, but they cause headache and lassitude among the performers. It is claimed that this apparatus solves the problem of continuous film production in Great Britain.

Permanent Statistics In The Power Plant

This is the Second Article in the Series Dealing With Power Plant Book-keeping. The Subjects Covered Are Depreciation and Insurance Charges, Rent, Management, and Maintenance Costs

By ROBERT JUNE

FIXED charges of the power plant are made up of a number of separate items such as depreciation, interest on investment, rent and administration. Maintenance consists of renewals and repairs, and the necessary labor required to make them.

Depreciation

Depreciation results from a decrease in value of a given piece of apparatus, as a result of wear and tear, age, changing plant conditions, and changes in the art of manufacture of the particular apparatus which renders its further use inadequate. A convenient classification of the various forms of depreciation follows.

Complete Depreciation

This results from a gradual and even decrease in value, as the result of wear and tear.

Obsolescence, Inadequacy and Destruction

Marked improvements in the design of certain types of apparatus may render the use of the older type uneconomical, thus prematurely shortening its life.

Inadequacy is the result of increased demands upon capacity, which renders it necessary to discontinue the use of a given machine, or the result of changing plant conditions which render the services of a machine of a given type no longer necessary.

Destruction is the result of accident. The possibilities of accident should be covered by insurance as fully as practicable. As they cannot be anticipated, it is difficult to set up a proper reserve for them. Obsolescence and inadequacy can, at times, be anticipated, and when this is the case definite reserves should be set up to compensate for them. Whether there is reason to expect them or not, some reserves should be set up in these days of rapid developments in the mechanical arts.

Incomplete Depreciation

This is due to unusual wear and tear of the sort which is apt to fall at irregular intervals in large amounts. Depreciation may be handled by several methods, as follows:

(1) To charge to earnings in good years and credit to depreciation such amounts as the profits from operation permit.

(2) To charge to earnings the depreciation as it matures and necessitates renewals.

(3) To charge to earnings and credit to depreciation reserve annually a certain percentage of the cost determined by the average weighted life of the property.

It is quite common practice in power plant work to set up an average annual depreciation and allowance, based on the original cost of the equipment, less its value as junk or salvage, and to spread this depreciation over a period of years approximating the assumed life of the equipment. Table 1 gives the approximate useful life of the most common type of power plant equipment, based on the assumption that they are properly handled and cared for, and that maintenance and repairs are kept up. This table does not account for obsolescence or inadequacy, and its figures should be discounted on this account.

Table 1

Approximate Useful Life of Various Portions of Steam Power Plant Equipment

	Years.
Belts	8
Boilers, water-tube	25
Boilers, fire-tube	20

Rotary converters	20
Soot Blowers	8
Storage batteries	15
Stokers	12
Turbines	25
Transformers	20
Wiring	15

If we consider depreciation as including maintenance, we should properly set aside as a reserve a fixed percentage for the decreasing value of the equipment to represent the unmatured depreciation. In this way we equalize matters by making the depreciation allowance larger when repairs are smallest and vice versa, depreciation smallest when repairs are largest, as the end of the useful life of the equipment approaches.

Depreciation reserves may be accumulated, therefore, either on the "straight line" or "sinking fund" method.

In the straight line method, if we assume that the total investment, less salvage, is divided by the expected life of the equipment, we will have the amount in money which should be allowed each year to cover the accrued depreciation. This is the simplest method. It is illustrated in Figure 1. Probable age of equipment may be determined from Table 1, with discounts as noted, to take care of obsolescence and inadequacy. In utilizing this method, the original cost is considered as including the net cost of labor and material, plus overhead, which includes insurance charges, fire and liability in-

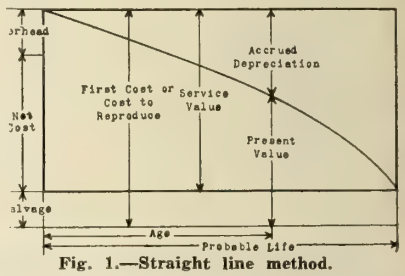

Fig. 1.—Straight line method.

surance, interest on investment during construction, installation, and, where the entire plant is being built, financial, legal and organization expenses.

Sinking Fund Method

In utilizing the sinking fund method, we set aside a fixed sum per annum, which must be allowed to accumulate at compound interest. The money thus set aside, plus accumulated interest, must be equal to the original cost of the equipment, less salvage value, at the end of the assumed life of the equipment. Again we have reference to Table 1 for the life of the equipment, and again we must make proper discount for obsolescence and inadequacy.

Figure 11 graphically illustrates a convenient method of determining the rate of depreciation in connection with

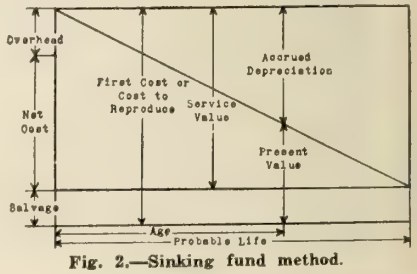

Fig. 2.—Sinking fund method.

the use of the sinking fund. Table 11 may be conveniently used in this connection.

Table II

Rate of Depreciation
Per Cent of First Cost

Assumed useful life	Rate of Interest, per cent						
Years	4	4.5	5	5.5	6	7	8
2	49.02	48.90	48.78	46.66	48.54	48.31	48.07
3	32.03	31.87	31.72	31.56	31.41	31.10	30.80
4	23.55	23.39	23.20	23.03	22.86	22.52	22.19
5	18.46	18.28	18.10	17.19	17.73	17.40	17.04
6	15.08	14.89	14.70	14.53	14.33	13.97	13.63

18	8.90	3.72	3.55	3.39	3.23	2.94	2.66
19	3.61	3.44	3.27	3.11	2.96	2.67	2.47
20	3.36	3.19	3.02	2.87	2.71	2.44	2.16
25	2.40	2.24	2.09	1.95	1.82	1.58	1.36
30	1.78	1.64	1.50	1.38	1.26	1.06	0.88

Interest on Investment

Interest on investment should cover not merely a percentage of the original net cost, but it should also include overhead, such as insurance, engineering fees, office charges, cost of superintendance, interest on money paid in advance of the operation of the equipment, etc., the point being to include everything which enters into the expense of putting the equipment into service.

If the equipment, or building, in the case of a complete power plant is covered by mortgage, or bond issue, the interest rate must be high enough to include the complete interest on the mortgage, or bond, as well as any differential between the total gross cost and the amount of the bond or mortgage.

If the new equipment or building is paid for out of surplus previously earned in the business, interest should be charged at the rate which the money would earn if invested in other branches of the business, or which it would earn if placed out at interest.

At this point, it is well to draw a distinction between repairs and renewals on one hand, and additions on the other. Repairs and renewals which do not increase the value or efficiency of the equipment beyond its former value must be charged to operating expenses. Additions, such as accessories which increase the value of the equipment, should be considered as capital investment. In the case of obsolescence or inadequacy, which has not been anticipated or entirely charged off in former years, only that portion of the cost of replacement above the cost of renewal of the old equipment should be charged to capital value. The remaining depreciation which has not been anticipated, must be charged to operating costs.

It should also be remembered that as depreciation occurs capital value declines, so that the amount of interest set aside each year will be less as time goes on.

Insurance

Three classes of insurance are usually required in the power plant. First, on the building; second, on equipment; and the third, liability insurance on employees. On the first two classes, the premium is in direct relation to the value of the plant and equipment. The premium on the third class bears no relation to the cost of physical equipment, being based on the cost of labor and the hazards of employment.

Description	Rate per hr.	Total hr.	Amount $	Remarks

Deductions for Construction and Repairs not for Power House

Description of work		Name of workman	Rate per hr.	Total hr.	Amount $
Location	Kind				
Total Deductions for Out of Power House Labor (C) $					
Grand total deductions for labor for non-operating purposes (B + C) $					
Net labor attendance costs A−(B + C) $					

Fig 3.—Daily report sheet for power plant labor.

Property Insurance

The relative premium on building insurance remains approximately the same year after year. However, it is extremely important to remember that when additions or alterations are made to the plant, that additional insurance should be provided. Changing replacement values of plant and equipment should also be taken into consideration. Thus, a building erected in 1912, for example, of good construction and with an estimated life of 40 years, would, in 1920, if building costs had remained the same as in 1922, be properly insured for three-fourths of its original cost. However, as building costs have approximately doubled in the past ten years, the insurance should be based on the replacement cost to-day, less depreciation, which would mean that the building should be insured at 1½ times its original cost.

Changing hazards must also be taken into account. If the fire hazard increases, the insurance companies will be found to be very prompt to cancel the policies in force and place in effect new ones at higher premiums. Should the fire hazard decrease, the owner should have the old policies cancelled and new ones issued, based on the lessened risk.

Equipment Insurance

Equipment insurance should be based on replacement value just as in the case of building insurance. If old machinery is replaced by new, the policy should be revised to take this new value into consideration in order to secure adequate protection.

Liability Insurance

Liability insurance has come to assume a very important place in power-plant costs. The premium, as a rule, is based on the pay roll, being divided however into a number of sections, each carrying a different premium depending upon the hazards of the individual class of work. As the premium may run anywhere from one to ten per cent of the actual cost of labor, it forms a very important item and should not be neglected.

The first point is to ascertain the exact amount of time put in by the various power plant employees on various classes of work, bearing different premiums. For this purpose a daily re-

port similar to that shown in Figure III is desirable. This, in addition to serving as a check on insurance premiums, may also be used for purposes of efficiency study in order to determine whether any undue proportion of time is being put in on certain classes of work.

In going into the various classes of insurance in detail, our purpose is to point out that insurance is much more of a variable than is generally supposed and that the insurance costs for a given period should not be assumed to be in definite relation to liability but that they should be ascertained exactly for the period covered by the cost analysis.

Building and equipment insurance is, of course, a fixed charge. Liability insurance is sometimes considered a part of the cost of labor and is simply added thereto as an operating expense. However, it is more simple to regard liability insurance as a fixed charge.

Rent

The value of the ground on which the power plant is built determines the amount to be charged up to rent. Where the power plant is merely one group of buildings, as in the case of a factory power plant, the rental should be in proportion to the amount of ground occupied by the power plant, coal pile, etc., as compared to the other buildings. Where the power plant stands alone, as in the case of a central station, the value of the entire real estate is based for rental charges. Here again we have to take into consideration changing real estate values. However, adjustment and rental charges need ordinarily be made not oftener than once a year.

Administration Figures

This covers such items as salaries of officers, clerical wages, office supplies, office rent, interest and depreciation on equipment, depreciation and repairs on office equipment, insurance on office equipment, postage and stationery, telephone and telegraph, legal expenses, and where power is sold as well, advertising and sales expenses. In the case of a central station, all of the above items should be charged against the cost of producing power. If the central station has other lines of activity, they must be proportioned in relation to the expenses incurred by the various departments of the business.

In the case of a factory power plant, power becomes a production expense and the overhead charged against the power plant should be in relation to the total investment, and also to the total labor expenses in the factory and the total labor expenses in the power plant.

With uniform production, administration expenses will ordinarily vary but slightly from month to month. It should be ascertained each month and figured into the cost of power. Right at this point, the writer enters the plea that the men in actual charge of the production of power be regularly supplied each month with a statement from the accounting department showing all the charges set up against the power plant for interest, depreciation, insurance, rent, administration expenses, and maintenance. These figures are all too commonly regarded as a secret. Just why this is so is not clear. The figures are usually of not the slightest value or interest to any one outside the plant nor would their possession by the operating men embarrass the management in 99 plants out of 100. Giving the operating men these figures indicates first, confidence in the integrity of the men and secondly, confidence in their ability to suggest ways and means of reducing some of these charges. Finally, it tends to curtail waste and extravagance where such exist.

Figure IV indicates a form of record which should be kept in the power plant, one sheet for each important piece of equipment. This is not a formal accounting record—its purpose is to keep the men in charge of power plant operations fully informed of the nature and extent of the investment and the various types of equipment and the cost of operating each individual unit. Its value will depend upon the individual men and their interest in their work.

Maintenance

Maintenance and repair costs records should also be kept in the power plant. Again, this is not for formal accounting purposes. Its value to the operating men is to tell them where they are at with respect to the cost maintenance of various types of equipment. Maintenance, of course, refers to the expense of keeping the plant in running order over and above the cost of attendance. It does not refer to the replacement of new units but it includes the cost of keeping the plant attendants, whose time would go on anyway whether they were engaged regularly on repair work or not.

Figure V offers in convenient form a means of keeping track of the maintenance costs in the power plant. One of these sheets should be used for each machine of any size and the accounting department instructed to place at the disposal of the operating men any needed information regarding the costs which will enable them to keep those records with approximate accuracy.

In the study of the distillation of Freeport coal being made at the Pittsburgh Experiment Station of the United States Bureau of Mines, duplicate samples of the bone and cannel constituents of the Freeport seam have been distilled at low temperature in 12-pound lots. A sample of the bottom section of the clean coal was also distilled. From a comparison of the yields it would seem that the bone and cannel constituents of this seam should be of too great value to be treated as refuse.

At the Pittsburgh Experiment Station, in connection with the investigation of coal-storage problems, coal has been exposed to excess air for three hours at 150 deg. C; the amount of oxidation products formed and the amount of oxygen absorbed are taken as a measure of the tendency of the coal to ignite spontaneously. The method has been tested on Newfield (Freeport) coal and Texas lignite with fairly consistent results.

The Mueller Mfg. Co., Sarnia, expect to have extensions to their line of steam valves perfected about April 1st. This will enable them to place on the market a complete line in this department, representing a new development in their industry.

The Designing of a Triple Riveted Butt Joint

Factor of Safety Must Be Allowed—Determining Proper Thickness of Boiler Shell Plate—Strength of Boiler Shell—Sketching Proposed Joint—Resistance Against Tearing and Crushing

*By L. T. RUTLEDGE

THE STEEL to be used in the joint spoken of in the previous article in the February 5 issue, should be tested in a testing machine in order to determine its ultimate tensile, shearing and bearing values, and the value of the elastic limit for each kind of stress. The following are average values for the ultimate strength of ordinary boiler plate: in tension 60,000 lbs. per sq. inch, in bearing 90,000 lbs. per sq. inch, and in shear 45,000 lbs. per sq. inch. In boiler design a factor of safety of not less than 5 should be used; this being the usual factor employed.

Example:—It is required to design a triple riveted double strap, butt joint for a boiler 66 inches inside diameter, the maximum boiler pressure being 160 pounds per square inch. It is required that the joint be at least 85 per cent efficient.

Solution:—The first step will be the determination of the proper thickness of boiler shell plate. The boiler is a hollow cylinder, in the walls or casing of which stresses are induced by the internal pressure. The internal pressure is transmitted undiminished in all directions, and acts with equal intensity on all equal surfaces and at right angles to those surfaces. We assume that the stresses resulting from the external forces are distributed uniformly over the cross-section of the boiler shell.

Strength of Boiler

We shall consider the strength of the boiler shell in two main directions, namely, longitudinally and circumferentially. The longitudinal stress is caused by the pressure acting on the end of the cylindrical boiler, tending to tear the shell transversely. For a state of equilibrium the bursting external force must equal the internal resisting stress. The bursting force is given b the area of the cylinder end multiplied by the unit pressure, that is

$$\frac{\pi}{4} D^2 P$$

Where D is the internal diameter of the boiler, and P the internal pressure in pounds per square inch. The area that resists the bursting force is the area between two concentric circles, one D inches diameter and the other D+2t inches in diameter. This area is practically the area given by multiplying the circumference D by t. The unit stress is St. Thus the total resistance is Dts. Now as stated above, for equilibrium

$$\frac{\pi}{4} D^2 P = \pi D t S$$

$$\text{Therefore } t = \frac{PD}{4St}$$

Next, let us consider the strength of the boiler in a direction at right angles to the above. The bursting force, in this case, is that which tends to lift one half of the boiler longitudinally from the other half. The bursting force is given by the expression PDL where L is the length of the boiler inside. Although the inside surface is a semi-circle in one direction, it is quite correct to consider the resulting pressures as those at right angles to a plane through the centre of the circle; the plane being the one passing through the sections of the shell where it resists the bursting force.

The area that resists the load consists of two rectangles, each t inches in thickness and L inches long, the two sections being 180 deg. apart. The resisting area is 2 Lt. The total resistance is

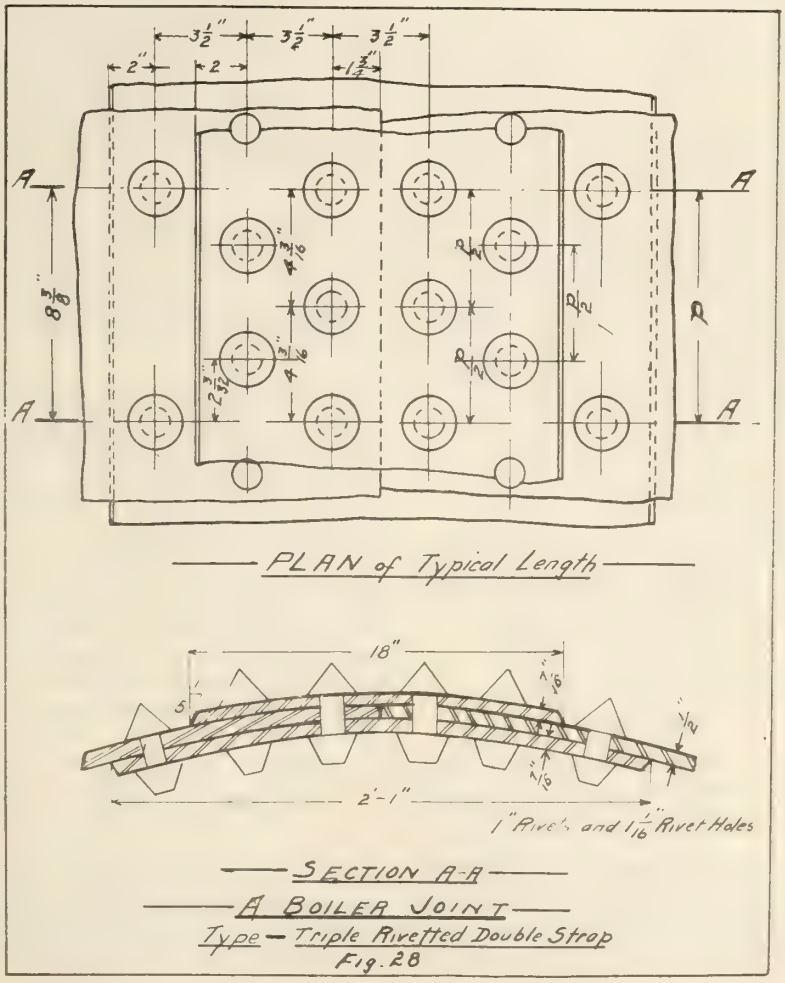
$$2Lt\,S_t$$

For equilibrium

$$PDL = 2Lt\,S_t$$

$$\text{Thus } t = \frac{PD}{2St}$$

It will be observed that this latter formula gives a thickness twice that given by the formula first obtained. This shows that if a boiler fails, it is altogether certain to fall along a longitudinal seam. So, for purposes of de-



PLAN of Typical Length

SECTION A-A

A BOILER JOINT

Type — Triple Riveted Double Strap

Fig. 28

*The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, Mr. Rutledge will be only too pleased to offer assistance. To save time, write direct to Kingston, explaining your trouble in detail.

sign and for safety, we shall use the latter formula, which gives the greater thickness.

Then, using the data given in the problem as stated, we have

$$t = \frac{PD}{2St} = \frac{160 \times 66}{2 \times 12000} = .44 \text{ ins.}$$

We use a factor of safety of 5; hence 12,000, being one-fifth of 60,000, (the ultimate strength of the boiler plate in tension) is the working tensile strength of the joint.

The boiler joint cannot be 100 per cent efficient. We are only required to make it 85 per cent efficient. This means that the joint is 85 per cent. as strong as the solid unpunched plate. So if we use the above value of "t" and have our joint 85 per cent. as strong as the clear boiler plate, it is apparent we shall not have a factor of safety of 5 in our boiler design as the joint will lower its value. The strength of the boiler is no stronger than the joint. Now, if we wish the joint to have a factor of safety of 5, let us make the plate thicker. If we consider 0.44 inches as 85 per cent. of the thickness to be used and find what thickness would be 100 per cent. then we have fulfilled the condition as regards the factor of safety.

Therefore the thickness to be used in the design is

$$t = \frac{0.44}{.85} = .50 \text{ ins.}$$

We shall, then, specify ½ inch boiler plate, which happens to be a commercial size.

The cover-plates or straps of a triple riveted butt joint for ½ inch boiler plate will be 7/16 inch, according to tables of standard practice as given in handbooks. The diameter of rivet that would be consistent with the thickness of plates to be used is 1 inch. Thus we shall assume $t' = 7/16$ in. and $d = 1$ in.

The diameter of the rivet hole; $d' =$ 1-1/16 in. The above assumed value shall be tested in the following solution, in order to ascertain if the assumptions are correct.

In the example, the following permissible working stresses obtained from the ultimate values by adopting a factor of shaft of 5 will be assumed:—

Tension 12000 lbs. per sq. in.
Bearing 18000 lbs. per sq. in.
Shear 9000 lbs. per sq. in.

The foregoing values are good average ones for boiler steel. In most cases the values are somewhat greater.

A sketch of the proposed joint should now be made, which sketch is quite similar to the illustration in Fig. 28. There will be three rows of rivets on each side of the butt joint and it is assumed at the beginning that the cover plate on the outside of the boiler does not have to be as wide as the inner plate since the pitch of the rivets in the outer row is made twice as great as in the middle and inner row.

The results given by the various calculations for strength will indicate if this is a correct design or not. Hence if the joints fulfill the specifications there is no reason to make the butt straps of equal width. Assume "P" to be the pitch between two rivets in the outer row. A typical length of joint on which to make the calculations will be that between the two similar sections marked A—A. The adjacent lengths are exact duplicates and similar for the entire length of the boiler.

In the analysis of the joint it is best to consider and determine the resistance against every possible failure in the typical length of boiler joint.

The various resistances against failure are:—

1. Resistance against tearing of the plate in the outer row:—

Using the previous notation, we have the resistance against this failure to be

$$P_1 = (p - d')t S_t \text{ ---- (a)}$$

Where $(p\text{-}d')$ is the length of solid metal between two adjacent rivets.

2. Resistance against tearing of the plate between the rivet holes in the second row combined with the failure of the rivet in the outer row, the rivet in the outer row falling either by shear or by crushing against the cover plate:—To express this correctly we need two algebraic equations, namely,

$$P_2 = (p - 2d')t S_t + \frac{\pi d^2}{4} S_s \text{ -(b)}$$

$$P_3 = (p - 2d')t S_t + dt' S_b \text{ ---(c)}$$

In the equations just established, it is well to note the first term. In the second rivet row in our typical length of joint between sections A—A two rivet holes occur. These are shown deducted in the equations.

3. Resistance against shearing of all the rivets:—In our typical length of joint on the one side we have in the second and inner row four rivets in double shear and one in the outer row in single shear. The total of these is equivalent to nine rivets in single shear, therefore

$$P_4 = 9 \frac{\pi d^2}{4} S_s \text{ ---(d)}$$

4. Resistance against crushing of all the rivets:—The joint may fail by the crushing of the four rivets of the second and inner row against the boiler plate, and the crushing of the rivet in the outer row against the cover plate. Then the resistance against this probable failure is

$$P_5 = (4t + t')\, d\, S_b \text{ ---(e)}$$

5. Resistance against combined crushing and shearing. The joint may fail by the crushing of the four inner rivets and the shearing of the rivet in the outer row. For this we have

$$P_6 = 4dt S_b + \frac{\pi d^2}{4} S_s \text{ ---(f)}$$

A joint of this type should be designed so that it becomes stronger as the center line of the joint is approached. This condition is obtained by making equations (b) and (c) greater than (a) that is

$$(p - d') < \frac{t}{S_s} p_{II} + \frac{2}{3} t (p_2 - d)$$

$$t S_t \text{ and } (p - 2d')t S_t + dt' S_b > (p - d')t S_t$$

For simplicity in this case, where absolute accuracy is not essential, assume d' equal to d, then by simplification of the above expressions we see that the condition is obtained if

$$d > \frac{4t S_t}{\pi . S_s} \text{ --- (g)}$$

which verifies our assumption for value of d in the first place and from the second expression we find that

$$t' > \frac{t S_t}{S_b} \text{ ---(h)}$$

The algebraic solution is completed. At this point we might insert arithmetical values in equations (g) and (h). Thus d must be greater than

$$4 \times \tfrac{1}{2} \times \frac{12000}{3014 \times 9000} \text{ or } .85 \text{ inch.}$$

Therefore a one inch rivet is satisfactory.

Also t' must be greater than

$$\tfrac{1}{2} \times \frac{12{,}000}{18{,}000} \text{ or } .33 \text{ inch.}$$

Therefore a 7/16 inch cover plate satisfies the condition.

The problem is to find the value of the pitch "P." To do this, determine the

resistances of P_4, P_5 and P_6 as given by equations (d), (e) and (f)

$$P_4 = \frac{9 \times 3.14 \times 1^2}{4} \times 9000 = 63617 \text{ Lbs.}$$

$$P_5 = \left(4 \times \frac{1}{2} + \frac{7}{16}\right) 1 \times 18000 = 43875 \text{ Lbs}$$

$$P_6 = \left(4 \times 1 \times \frac{1}{2} \times 18000\right) + \frac{3.14 \times 1^2}{4} \times 9000$$

$$= 45088 \text{ Lbs.}$$

The minimum value is that given by P_5, namely, 43,875. Equate P_1 to this value in order to determine the quantity "P."

$$43875 = (p - d')t\,S_t \text{ or}$$

$$43875 = \left(p - 1\tfrac{1}{16}\right)\tfrac{1}{2} \times 12000$$

$$\text{therefore } p = 8.36 \text{ or } 8\tfrac{3}{8} \text{ Approx.}$$

Therefore P=8.36=8⅜ approx.

We shall use the value 8⅜ but before adopting it finally, we must determine the values for P_2 and P_3 with P=8⅜. On substitution in equations (b) and (c) we get

P_2=44,568 lbs. and P_3=45,375 lbs.

It will be observed that the resistance as given by P_4 and applied to P_1 is the minimum value, the value being 43,875 lbs.

The efficiency of our joint as designed is equal to the minimum resistance or the strength of solid plate of length equal to pitch.

$$= \frac{43{,}875}{8\tfrac{3}{8} \times \tfrac{1}{2} \times 12{,}000} = \frac{43{,}875}{50{,}250} = .876$$

Thus the efficiency is 87.6 per cent. which is a little higher than the specifications called for.

The detail of the joint may be completed as shown in Fig. 28. The position of the gauge lines should be clearly dimensioned. The long pitch is 8⅜ins., the short pitch is 4-3/16 ins. The back pitch should be about 70 per cent. of the short pitch. This is given as 3½ ins. For boiler work, the marginal distance should be 2 ins. where 1-inch rivets are used.

Suggested Problems

1. Determine the pressure that may be safely carried in an air receiver 60in. in diameter, the shell of which is ⅜in. thick. The longitudinal seam is of the triple-riveted butt joint type having two 5/16 in. cover plates. The rivets are ¾in. in diameter and the pitch in the outer row is 6½in. The back pitch is 2-7/16in. and the margin is 1-7/32 in. The permissible working stresses for tension, shearing and bearing are 12,000, 8,800 and 19,000 lbs. per sq. in. respectively.

2. A pressure tank 48in. in diameter is subjected to an internal pressure of 150 lbs. per sq. in. Design a double riveted lap joint for the longitudinal seam of the above tank assuming the same working stresses as given in problem 1.

REFRACTORY CEMENTS

By W. S. Quigley

The title I have chosen for this brief paper is purposely selected to bring out a point with reference to high temperature cements on which there is some misapprehension. A refractory cement is not itself just a refractory but bears its title from the fact that it is used as a binder for refractories. There is probably not a commodity used to-day by manufacturers in general that is as little understood or as much overrated as are high temperature cements.

In foundry circles there has been a great deal of educational work during the past two or three years on the use of refractory cements, and while their successful application is well understood by many foundrymen there remains much information yet to be uncovered on the whole subject of their many and varied uses. This use sprung up rapidly during the war owing to the necessity for using material having refractories which, by increasing the life of linings, would prevent shutdowns and by the use of which repairs to furnaces could be quickly made.

Four Classes of Bonding Materials

Bonding materials may be divided into four classes.

First we have fire clay, the primary function of which is to compensate for the inequalities of the bricks or shapes as a pliable refractory filler, and with which unduly thick joints generally are made. It has no binding strength of itself unless subjected to a vitrifying temperature. For the material itself there is no definite recognized standard or specification so that the user is dealing with a varying commodity. Furthermore, since heat is required for vitrification in order to obtain a bond, it is obvious that only a surface bond is obtained, as the required heat for vitrification will not penetrate the entire thickness of the wall. The result obtained may be likened to a vitrified shell with a weak structural backing. Furthermore, the shrinking of the fire clay due to its own moisture and the combined water used in mixing it, causes a separation between the bricks or shapes in walls or arches which frequently results in bulging walls or collapse of the whole structure.

Secondly we have coarse grades of mixed materials or so-called cements which also have no binding quality, depending upon heat or vitrification for a bond. Materials of this class must be made to bind or fuse at approximately the same temperature at which the furnaces are run, or no bond is effected. In other words, a cement which is good for a low temperature annealing furnace is not good for a high temperature forging furnace, or vice versa. Such mixtures are subject to the same surface bonding result as fire clay.

Thirdly, some cements in order to hold the component parts together depend upon a fibrous structure which shrinks and eventually loses its binding value as soon as subjected to any considerable degree of heat. Such cements must lose their effectiveness as the temperature increases.

An Ideal Cement

Finally, to be universal in its application, a cement should air set and not depend upon heat for creating the bond in order to form a union throughout the structure. It must be passed through a very fine mesh sieve so as to contain coarse particles which would tend to create voids between the brick which it is used to bind. It should not shrink when subjected to heat. It should be a material which can be used as a binder with crushed fire brick, old crucibles, fire sand or fire clay, ganisters, and for making rammed-in linings, and doing repair work, hot or cold. And furthermore, its composition should be such that it can be used in neat form for making small hot patches and repairs.

The principal essential of a refractory cement is that it should have at various temperatures, the same co-efficient of expansion, as nearly as possible, as the materials with which it is used for bonding. Refractories themselves differ in expansion co-efficient, as in the case of fire-clay brick and silica brick, where the former has 0.075-inch and the latter 0.175-inch per foot at 2,200 degrees Fahr. Yet a cement with a co-efficient which lies between these two could be advantageously used with both refractories.

The difference in the cost between fire clay and high temperature cements must be justified by the difference in the results obtained.

Members of No. 1 Lodge are requested to forward their due cards to the secretary, Mr. R. Edwards, 47 Afton Avenue, at their earliest convenience, for the purpose of the auditors.

CANADIAN STOKERS SOLD IN THE U. S.

It is interesting to note that a Canadian firm, the Canadian Stoker Co., Galt, Ont., have been successful in selling their stoker equipment to the Standard Underground Cable Co. of Perth Amboy, New Jersey, for a battery of sixteen boilers. Four of these stokers have been installed, and the remaining twelve will be proceeded with shortly.

Should The Law Be Changed?

THE CORRESPONDENCE that has been carried on in the columns of Power House relative to the advisability of making the engineer's certificate a Federal instead of a Provincial document, has about run its course. The consensus of opinion seems to be in favor of making the change, but, of course, it must be borne in mind that those writing on the subject form but a small proportion of the total number of engineers in the country. Against this may be held the fact that they also represent the members of the profession who think about their status, and are anxious to improve it.

To our mind, there is no question of the advantage to the engineer in being possessed of a qualification from an authority that would hold good all over this broad Dominion. As it is under present conditions, an engineer who might wish to remove to some other province, if he is a man with a family, must hesitate a long time when he considers that the move may necessitate him starting at the bottom again, after, perhaps, many years spent in working up. Conditions may be such in his private life that he has no alternative but to make the move. The climate of one part of the country may be unsuitable to him or his family, or the prospects of advancement may be so small in the part he lives in that it may be advisable to seek a broader field. In this latter case, he is automatically handicapped by the fact that his previous experience and his present qualification may not count for anything in his new environment.

The question of recognizing qualifications from outside of Canada seems to exercise the thoughts of a good many correspondents, and the one that is in most of their thoughts is that of the British Board of Trade. It is not our intention to go into the merits or demerits of this particular certificate, but we might point out what is the attitude of the British Board of Trade itself to members of other parts of the Empire and even to those who are not British subjects. As long as these men have the necessary experience, the same as is demanded from candidates who are natives of the British Isles, they are allowed to sit for the examination without any discrimination. It is a notorious fact that before the war there were hundreds of aliens sailing in British ships holding British certificates granted upon examination by the British authorities.

The Britishers who were displaced by these men, grumbled against the shipowners who would employ foreigners in preference to their own countrymen, but we never heard them suggesting that they should not be allowed to sit for examination.

The Dominion Government could put any safeguards it felt to be necessary on the examinations, but we do not think that the majority of Canadians would wish to exclude their fellow Britishers from other parts of the Empire from the privilege of sitting for examination.

The adoption of a Dominion certificate law would mean that a candidate's examination papers would be passed on by a central authority in Ottawa who would not know even the name of the candidate. All he would see would be the paper written by the candidate, which would be numbered by the examiner in the town in which the candidate sat, and forwarded to Ottawa for judgment. In this way there would be a standard examination, and everyone would get the same chance. It does not mean that every examination paper would be the same, but the subjects would all be based on a common standard.

The condition which now exists, where every province has its own laws and its own standards, no two of which are alike, is unfair to the engineers themselves and to the employers of engineers.

This country is large in extent but small in population. Cutting off the provinces from each other by artificial barriers will not help it any. If engineers could circulate from coast to coast with freedom, they would not only be widening their own knowledge, but the knowledge of those with whom they come in contact.

A Dominion wide certificate would raise the standard of the stationary engineer all over the country, and attract many bright young men to the pursuit of stationary engineering who see no prospects in it under conditions that practically restrict them to the province they happen to be born in.

Our Question Box 37

Electrical Section 39

The Operators' Point of View

CO_2 AND TEMPERATURE

The Editor, "Power House"

I have taken up the subject of Mr. McLaren's articles on exit gas temperatures and excess air with Mr. F. A. Combe, M.E.I.C., consulting combustion and ventilation engineer of Montreal, and he says:—

"I cannot see where there is any confliction or disagreement between the theories mentioned by Mr. Pratt and Mr. Fisher regarding the influence of excess air on exit gas temperature." With this I fully agree.

Mr. Pratt gives one explanation, as that commonly accepted, that the excess air absorbs heat more readily than the boiler surface but he also states in the same paragraph that—"the other factor leading to such a result is dependent upon heat transfer rates, difference in temperature between the gases and the absorbing surface, the percentage of total heat absorbed through radiation and the percentage of total absorption through convection." Mr. Fisher dwells on these latter theories but there is no question of disagreement, — probably each factor has an influence.

In either case if the effect is the same, tests taken can be said to prove any theory put forward.

Mr. McLaren stated that some authorities hold that excess air lowers exit gas temperatures. It will do so, of course, if the air dilution or leakage is sufficiently excessive, but, within the range of average efficient operation, the temperature will increase with lower C. O.$_2$ Tests which I have taken show some similar results to those given in the article.

The formula given in Mr. McLaren's article for excess air is approximately correct only for burning of carbon, or anthracite and will not give true results for bituminous coal, owing chiefly to the influence of the hydrogen and moisture content. Thus referring to the two tests taken from Mr. Fisher's article, the excess air is 76 per cent. and 119 per cent. whereas the formula

$$\frac{20.7 - CO_2 \times 100}{CO_2}$$

would give 99 per cent. and 113 per cent. which is quite different.

The general method of determining the excess air from a gas analysis is to take the Nitrogen percentage as 100—(CO_2 + CO + O) and use the formula

$$\frac{N}{N - 3.782\ (O + \tfrac{1}{2}CO)}$$

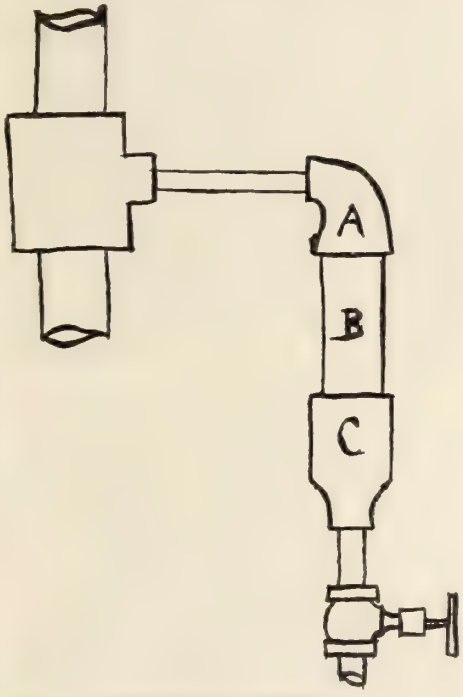
This formula gives the ratio of air actually used to that required for perfect combustion, and the excess air will therefore be 1 minus this ratio.

Mr. McLaren's formula should read 20.9 instead of 20.7 and is 175 per cent. 57.1 per cent., 49.3 per cent. for readings A. B. C. excess air.

HENRY WRIGHT.

A LUBRICATOR CONDENSER

Some lubricators are supplied without condensers, the idea being that a long pipe will be used. Sometimes it happens that there is no head room for a long pipe. Some engineers claim that a lubricator so installed will not give



Lubricator Condenser

the desired regularity of feed immediately after filling, that a short, large diameter condenser will.

By using a reducing elbow and a reducing coupling and a nipple, A B C as shown, a very good condenser is made.

DOMINION WIDE CERTIFICATE

Editor, Power House

It is with great interest I read the many interesting letters written to your valuable magazine re Dominion-wide Certificate. I am also pleased to see that the majority of the engineers are in favor of the same, which I sincerely believe would work out very satisfactorily.

I have worked as operating or construction engineer for the past twenty-three years having made several trips to the Pacific coast which has given me a pretty thorough knowledge of working conditions through Canada.

Regarding Mr. Goepel's objection to the certificate on account of the logging industry I don't think there are many stationary engineers that would care to handle a logging donkey. Therefore, I say leave them in a class of their own and continue to issue the certificate covering that particular work.

There is no doubt in my mind that the average engineer in Ontario to whom is given a certificate to operate a steam crane, shovel or mine hoist, would be capable of handling any logging donkey I have seen; and I am quite able to testify that some of them were built to make a heavy pull breaking a 1⅛ inch steel cable on test.

In conclusion, I would say, I have found conditions through Canada for the stationary engineer much the same, except the heating end of the game. I have installed plants on the Pacific Coast which did not require any installation for heat, but not so in Northern Ontario or some of the other colder provinces.

A. E. GEORGE

Amherstburg.

Editor, Power House:—

With reference to the above subject on which you invite opinions, would like to make a few comments. There is no question of it being a good thing, but to make a Dominion certificate a success there is one important condition that must be fulfilled. That is, that the highest standard of qualifications at present in use in any of the provinces should be taken as the standard for the new Federal certificate. In other words, no province should have to reduce its standard to comply with a Dominion Act. For two reasons this would not be right, viz., it would be detrimental to the craft as a whole, and it would not be fair to those engineers who have qualified and passed exams under just and strict provincial acts.

We, in the west here, think we have the best acts in Canada, while there are those in the east who think the same of their own; and a discussion of the

different provincial qualifications should result in a better understanding of what is required in an act of this scope.

Notwithstanding the opinion of your correspondent, J. W. C., to the contrary, in Power House, Jan. 5th, (who by the way does not say which province he is coaching in), there are some parts of Canada that have engineers' qualifications that compare most favorably with the British B. O. T. requirements for marine engineers, both as to shop time and operating experience. In the following comments the writer is not trying to put over a slam at the B. O. T. regulations; as used by the B. C. Examination Board, with the marine stuff cut out, they are strictly alright. But, when an engineer like J. W. C., who happens to hold a B. O. T. certificate, makes such sweeping assertions re Canadian certificates, it is up to some Canadian to fill up the gaps in his education along these lines.

He says he might have half a dozen of our certificates if he cared to house them. Is he referring to firsts or fourths? If he will come out west and try the B. C. and Alberta first class exams., he may possibly reduce the half dozen to four. He also says, "here in Canada anybody can go and sit for papers and get away with it." Evidently he does not know the qualifications for first class engineers in these most western provinces; and also, he has forgotten that he, himself, failed to "get away with it" judging by his experience where he was refused a certain Canadian certificate, or even the chance to try the examination, although he was the holder of a B. O. T. certificate.

According to J. W. C. "things are done differently in the old country." Yes, they certainly are. They are done so differently that it is not necessary for the engineer of a steam plant to have a certificate at all. This does not apply to marine work, of course. Perhaps this will explain his statement that old country ads. for engineers usually state a preference for marine engineers; or in other words, those who have taken an examination are preferred to those who have not. No longer ago than the Jan. 20th issue of Power House we have an example of how "things are done differently in the old country," where there is an account of an accident due to ignorance in draining a steam line. It is summed up as follows by the B. O. T. Surveyor-in-Chief: "The conditions obtaining at the time of the explosion clearly point to the action of water-hammer as the cause; and it would appear that *those in charge of the plant were not apparently aware* that the clearing of water of condensation from a range of steam pipes whilst in open communication with the boiler is a most dangerous practice."

If J. W. C. does not think Canadian certificates are worth the paper they are printed on, he should use reasonable caution in coaching pupils for these worthless scraps of paper. Also, he should not overlook steam turbine information, as even in the second exams. of Alberta there are questions on this important part of engineering, although he has never seen any in the exams. of the province in which he lives.

The writer has had considerable experience during the last fifteen years with both B. O. T. and Canadian engineers, and there are good and bad in both classes. Each has something to learn in taking up the other's work.

Again in the Jan. 5th Power House, Mr. Livingston compares the certificates of B. C. and Sask., and appears to have very little use for the former. His statements require a little supplementary information. The big trouble seems to have been the hiring of some returned soldiers with temporary certificates in B.C.

In the first place, the plant referred to is a T. B. sanitorium, and this may explain why a man with a temporary certificate was "hired at a salary considerably higher than the average paid in the province at the time." There are lots of people besides licensed engineers that would not care to work around an institution of this kind.

In the second place, a B. C. "temporary" is issued only upon the recommendation of the inspector in whose district the plant is situated, cannot be renewed, is good only for one year and only for the plant specified thereon. It is not reasonable to suppose that an inspector would recommend a man for one of these certificates without ascertaining to his own satisfaction that the man would be a safe one for the work required.

On the other hand, the Alberta and Saskatchewan "Provisional" certificate is good for any plant up to 50 h. p., can be renewed several times in the case of traction work, and is also issued upon the recommendation of the district inspector after an oral examination. To quote Mr. Livingston's words, re the B. C. "temporary," an engineer with this provisional certificate could work a year and then "pull out in time to escape the examination." Or he might feel like having it renewed.

Mr. Livingston also states that there is "not enough writing and too much verbal" work in the B. C. exams. as compared with Saskatchewan. If he ever sits for either a second or a first in B. C., he will likely change his mind regarding this; three days "writing" and one day "verbal" ought to satisfy him.

Another point in the B. C. Act that Mr. Livingston would have changed is the elimination of the third and fourth class certificates. Well, this is a change anyway from the engineer in the east, who some time ago advocated "scrapping" the B. C. firsts and seconds, as "they were too hard to get." The writer has heard the B. C. license law called everything from "too strict" to "the Robbers' Corporation," but this is the first time he has ever heard of an objection to the lower grades.

If the thirds and fourths were cut out as Mr. Livingston advocates, employers would have to pay more and hire engineers that would be real scarce for small plants. Also, the engineer that could not take the second or the first exam. would have no chance to run a small plant himself, and thus get more practical experience, but would have to depend on a "stand-in" with some chief for a job. This vision of Mr. Livingston's would also mean that in the absence of the engineer-in-charge, the plant could be under the care of a man that, as far as the law was concerned, might have served his apprenticeship selling lace and silk stockings to "chickens." As long as the chief of the plant thought him a good engineer, he would be alright.

In conclusion, Mr. Editor, it is the writer's opinion that neither J. W. C., Mr. Livingston, or any fair-minded person can pick many holes in the B. C. Act or its administration. It is the daddy of them all in Canada. The exams. and qualifications are equal to the British B. O. T. standard, and in framing a Dominion Act, the B. C. and Alberta ones would be good ones to shoot at.

J. A. C.

Editor's Note

There does not seem to be any need for prolonging this discussion further. The consensus of opinion of those writing on the subject is that a Dominion-wide certificate would be a good thing for the majority.

We regret being unable to publish the letters received from two correspondents this week, but would point out to those gentlemen that their letters really had no bearing on the advisability or otherwise of the Dominion certificate. If the majority of the engineers feel that there should be a federal instead of provincial certificate, then it is up to them to move in the usual constitutional manner to obtain it. If they are satisfied as things are, there is no more to be said. There would need to be a pretty efficient organization to bring about any change and it would be a long fight against the susceptibilities of the provincial authorities.

The waterworks commission of Brantford, Ontario, plan for an addition to their pumping station including installation of three gauge centrifugal pumps with electric motors.

At the February meeting of the Toronto Association of Purchasing Agents an interesting talk on "How to Buy Coal" was given by the guest of the evening, E. C. Hanson The subject was received with great interest, in view of the threatened coal strike on April 1st. The annual election of officers of the association will take place at the March meeting.

To complete the plans for the successful manufacture of Saskatchewan lignite on a commercial basis, Hon. Charles Dunning stated that it would require an additional $250,000 to carry out the work. About $800,000 has been expended to date. It is expected that the required money will be granted jointly by the Federal Government and that of the Provinces of Manitoba and Saskatchewan.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

SQUARING CRANK SHAFT

Question:—Please explain how to set a crank shaft square with the cylinder of a gas engine die of cylinder 17 in. x 25 in. stroke. Double web crank, horizontal type. There is a fly-wheel on the shaft about 9 tons with outer bearing.

I may say the centre bearing has been welded at a crack and has been reduced in diameter, so bearing has to be rebabbitted.

Answer:—Remove the piston and connecting rod from the engine, and stretch a line through the cylinder exactly in the centre, carrying it over to an upright or some fixed point just beyond the throw of the crank. In order to get the line right in the centre of the cylinder place a straightedge across the mouth of the cylinder and fasten the string exactly in the centre as found by careful measurement. In the head of the cylinder where the rod comes through place a piece of wood on which is nailed a small piece of tin, and mark on this tin the exact centre of the hole, this spot just enough for your string to pass through. Fasten the end of the string to the upright at the crank end, using a spirit level to make sure that it is straight from where it leaves the cylinder. This is the exact centre line of your engine. Now turn the crank round until the crank pin just touches the string, and calliper on each side of the string to see if it comes directly in the centre of the crank pin. Then turn the crank round on to the other centre and again measure the crank pin each side of the string. If the string lies exactly in the centre of the pin on each centre your crank is square. If not, the crank shaft must be adjusted in the bearings until it shows true.

A PIPE SCALING PROBLEM

Question:—We have a peculiar case in the plant I am in of a pipe scaling up on a steam line. There is a 12-inch header which carries two tees, one of them leading through a valve to a four inch line which supplies steam to the feed and vacuum pump. This four-inch line is taken off the top of the header, the outlet of the T looking upward, and there is a valve, then an elbow, and the four-inch runs from the elbow horizontally, being tapped for the feed and vacuum pumps. The four-inch has a little dip after leaving the elbow, but only a slight amount.

This pipe has on two successive occasions choked up to such on extent that it will not supply the pumps, not with soft scale but with scale of such tenacity that it has to be chipped out of the pipe with a hammer and chisel. I would like to have your opinion of the cause of this scaling, and why it should appear in that spot. We have Wickes boilers, and the steam is pretty dry, pressure being 125 lbs. per sq. inch. There is not much scale in the boilers, or any other place outside. My opinion was that the header was so much larger than is required to supply the pumps that there is very little circulation of steam through the four-inch header, and whatever scale-forming elements there are in the steam attacks the ell at this point.

Are there any scale forming elements left in water that has once been steam?

Answer:—This is a peculiar case, but we would be inclined to the opinion that the scale formation is more likely to be the result of oxidation caused by the settling of very hot water in this particular spot. There may also be some small particles of scale carried from different parts of the line which also settle down in this spot and combine with the scale or rust formed by the condensation in this point. There should not be any solid matter in the condensate formed from steam of this temperature. We would like to hear some other opinions on this matter.

FLUE GAS ANALYSIS

Question:—What is the basis of flue gas analysis and on what principle do CO_2 machines work?

Answer:—Flue gas analysis is for the purpose of determining what proportion of the gases leaving the boiler are carbon dioxide, the proportion of carbon monoxide, and the proportion of oxygen. By this means the relative perfection of combustion, and therefore the efficiency of the furnace is arrived at.

The basis of flue gas analysis is as follows: In order that a pound of carbon shall be burnt to carbonic acid gas or CO_2, with perfect combustion it must be mixed with a proportion of oxygen, actually 2⅔ pounds. As oxygen is not procurable alone, but is contained in air, we must use enough air to burn our pound of carbon as will contain the necessary oxygen. Now as air is composed of oxygen and nitrogen, the nitrogen being about 79 parts and the oxygen 21, it follows that we must use considerably more air than oxygen, and the actual amount of air necessary to supply the required oxygen is 11.52 lbs.

Now this would be enough if it were perfectly mixed with the carbon, and we would have perfect combustion. This cannot take place in a furnace and the result is that we have to use more than the 11.52 lbs. air to supply the necessary oxygen. The closer we can keep to the theoretical amount the more efficient we will be, and it is to determine how close we are keeping that the method of gas analysis is resorted to.

When the oxygen unites with the carbon in the proportion of 2 parts of O to one of C and makes CO_2, the volume of the gas remains the same. That is, there is the same volume of CO_2 as there was of O before the mixing takes place. Now if we have 100 parts of air of which 21 are oxygen before mixing with the carbon, it follows that had we just enough air to cause perfect combustion, we would afterwards have 21 parts of CO_2 and 79 nitrogen. Thus, then, we arrive at the fact that with perfect combustion we should have in the flue gases 21 per cent. CO_2. This would however only be the case were the combustible pure carbon. This is what the flue gas analysis is based upon.

If combustion has been imperfect we shall have instead of CO_2 and nitrogen, some CO or carbon monoxide, showing there has not been enough air to support complete combustion.

If combustion has been complete but we have used a much larger quantity of air than was necessary we shall have a smaller proportion of CO_2 as compared with nitrogen, and we will find oxygen present in the gases also if we look for it.

The amount of CO_2 wil show us approximately how much excess air we have used. Suppose that the analysis shows 12 per cent. CO_2 and the highest possible with the fuel we are using is 18 per cent. Then 18—12=6 and 6 divided by 12 gives .5 which multiplied by 100 gives 50 per cent. and this is the amount of excess air.

All flue gas recording machines are built upon the properties of certain material for absorbing the gases of combustion. Thus caustic potash absorbs CO_2. If a sample of gas from the flue is drawn through the machine and measured, and then passed through a vessel containing caustic potash, the CO_2 is absorbed. If the sample is then

passed to the first measuring chamber again, there will be a difference shown which is the amount of CO_2 absorbed. This will be shown on a calibrated scale made on the instrument. The design of the various machines is of course different, and the methods of making the record, but the general principle is the same in all.

WET AND DRY THERMOMETERS

Question:—What is the action of a wet and dry thermometer and how are they read to determine the proper amount of relative humidity?

Answer:—Air contains always a certain amount of moisture in suspension. At every different temperature and pressure of air there is a definite amount of moisture that can be carried by the air. The relative humidity is the amount of moisture contained in the air compared to the possible amount it could carry. In other words you may say that the saturation point of air is 100, and the actual amount in the air at any time is the quantity compared to 100, or the percentage. The method of determining the relative humidity is by means of a wet and dry bulb thermometer. The dry bulb thermometer is the ordinary thermometer we are used to. The wet bulb is, as far as the thermometer itself is concerned, the same, but around the bulb there is a small amount of damp cloth.

The wet bulb thermometer should be in a current of air, or should be moved around in the air when a reading is being taken, so that there is a circulation around the bulb. The theory is this. The damp cloth around the bulb of the thermometer will, if the air surrounding it is not saturated, have some of the moisture evaporated by the surrounding air, and the result will be lowering the temperature of the thermometer. Now it will be plain if the air is already saturated, or at 100 per cent. humidity, it will be impossible for any of the moisture to be evaporated, and the wet and dry thermometers will read the same.

The less the difference between the two readings, the greater the amount of humidity in the air. The greater the difference the less humidity is carried in the air. As the temperature of air rises, its capacity for carrying moisture increases very rapidly, and it is this high content of moisture with the high temperature that makes things so uncomfortable for us in what we call sticky weather. When the air contains a high percentage of humidity the body cannot evaporate the perspiration from its surface and we suffer much discomfort.

The usual limits of humidity are between 50 and 75 per cent., and the closer it can be kept to the lower limit the better it is in general.

In order to obtain the relative humidity from the reading of two bulbs it is most convenient to use a table, such as the one given below.

AIR VESSEL ON SUCTION

Question:—What benefit would be derived from putting an air chamber on the suction side of a water pump? Kindly answer through the "Question Box."—J. McC.

Answer:—The air vessel on the suction side of a pump serves the same purpose as it does on the discharge side, that is, to provide a cushion, and lessen the shock from the pulsating of the pump. In case of a pump with a long suction pipe, running horizontally or even with a slight drop to the pump, the water, when set in motion, possesses a good deal of inertia. With the alternating reversal of direction of the plungers, surges of the column of water in the suction pipe are liable to be set up, and the provision of an air vessel supplies the means of taking up these surges. You may see the same thing in a very much exaggerated form in the surge tanks provided on the penstocks of hydro electric installation. If a penstock gate is closed down either partially or fully, while a turbine is running, the inertia of the moving column of water in the penstock would inevitably carry something away if some relief were not provided The surge tank, which is a large vertical tank of from 30 to 50 feet in height, provides the necessary relief by allowing the energy of the water in motion to lift a column of water in the tank, which thus acts as a safety valve.

On a small scale the air vessel, on the suction side of the pump, performs the same function.

At the Central District Station of the Bureau of Mines at Urbana, Ill., laboratory work on the distribution of sulphur forms at certain mines in the Illinois No. 6 bed has been completed. Sulphur forms have been determined in the raw coal, clean coal and refuse resulting from washing this coal on the S. S. & S. table at Dallas and on specific gravity fractions.

BULLETINS

We have received from the B. F. Sturtevant Co., Boston, Mass., their bulletin, No. 246, describing their generator cooling apparatus. This bulletin is well illustrated and describes the details and general arrangement of the air washers and fans as applied to this particular form of ventilating. The special atomising type nozzles are clearly illustrated, and a psychrometric diagram for determining relative humidity is given.

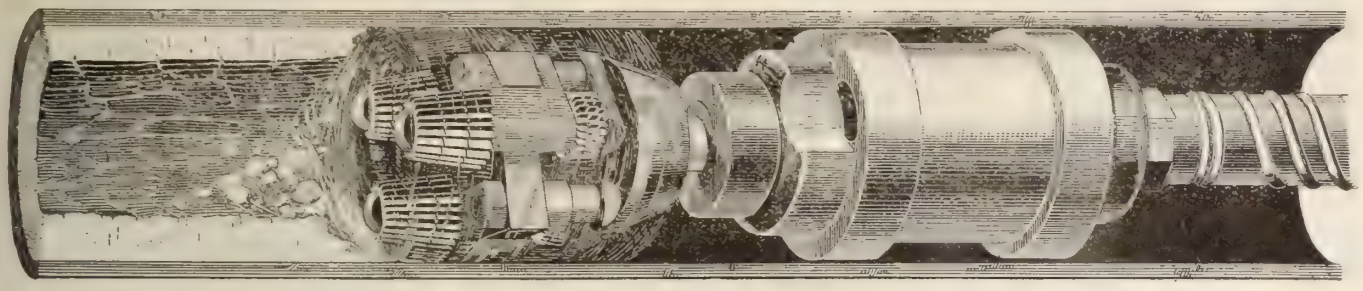
The Ingersoll Rand Co., have issued a bulletin describing their low level multijet type condenser. The booklet goes very thoroughly into the design and principle of this type of condenser, and its advantages are pointed out in a very clear manner. There are several illustrations of actual installations, as well as diagrams showing the construction of the unit.

The Canadian Ingersoll Rand Co. have issued a new bulletin describing their Price-Rathborn Oil Engine. This is a fourstroke cycle engine, vertical, with direct injection. There is thus no air compressor for fuel injection. A high economy is claimed for this engine. The bulletin contains a number of illustrations showing the construction of the engine, and typical indicator cards are included. The details of the engine are also shown, as well as some photographs of actual installations.

The Payne Dean Ltd., New York City, have issued a leaflet bulletin describing their electrical control for steam and water valves. The bulletin sets forth what the requirements for the efficient control of valves by electrical means are, and in what manner the Dean control unit fulfils these requirements. These control units are operated from any position either remote or close to.

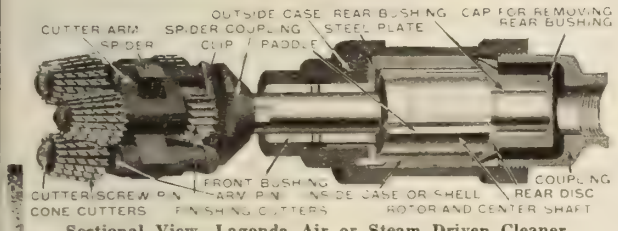
The Simplex Valve & Meter Co., Philadelphia, have issued a bulletin describing the method of making waste water surveys by means of their Simplex Pilot Tube, Portable Manometer and the Simplex Portable Chart Recorder. The waste water surveys are for the purpose of checking water leaks on water systems. It also serves to check up the slip on the pumping engine. The mode of operation is described in this bulletin. The same company have also issued a bulletin describing their Simplex boiler feed meter, which is built on the well known Venturi tube system.

We have received from the Goldie & McCulloch Co., Galt, a bulletin describing their new Type H water tube heating boiler. This boiler resembles in design to a great extent the standard cross drum type water tube boiler made by the same firm, excepting that the headers are in box form. The boiler is readily installed in even cramped quarters, as it can be shipped in knocked down form, and assembled right on the foundations in the factory or building it is going to heat.



Scale is Too Expensive a Luxury for *Your* Plant

LAGONDA TUBE CLEANERS

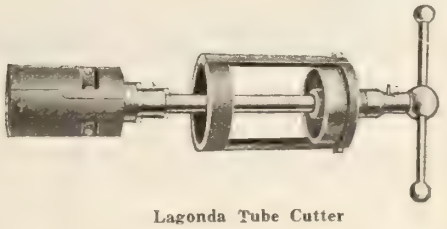


Sectional View, Lagonda Air or Steam Driven Cleaner

Lagonda Boiler Tube Cleaners are built right in every detail. They are fast, but thorough, long-lived, simple in construction. The above illustration shows a sectional view of the air or steam driven Cleaner.

Lagonda Cleaners are made to be driven by air, steam or water, and in all sizes for straight tubes or curved, in fire tube or water tube boilers. We will gladly send catalog and give full particulars.

LAGONDA TUBE CUTTERS



Lagonda Tube Cutter

Cutting boiler tubes is a simple operation when you are equipped with a Lagonda Tube Cutter. It makes a quick, clean cut, may be operated by one man and can be equipped with extension shaft for cutting tubes at any point. Descriptive bulletin and full information upon request.

Practical Electricity for the Power Plant

By Geo. R. Archdeacon, A. M. I. E. E.

HAVING briefly explained how Magnetism and Electricity react on each other, we will in this chapter consider the application of this phenomenon to practical things.

Every wire carrying a current of electricity develops a "magnetic field" immediately round it. If however, we form the wire into a coil and connect one end to the positive pole of a battery and the other end to the negative pole, a current will flow round the coil, this will develop magnetic lines of force within the coil.

The lines of force will extend outwards from each section of the wire in the direction shown by the short curved arrows in Fig. 1. The wire in the coil of wire being near together, all the different "magnet fields" (developed by each turn) will overlap each other, and by their action upon each other all lines of force within the coil will be turned in one direction, as shown by the long arrows in Fig. 1.

Such a coil is known as a "solenoid," and a piece of iron presented to the end of the solenoid is immediately "sucked" up inside the coil. This principle is frequently taken advantage of in the practical operation of various automatic systems of starters and regulators.

It must be apparent that such principles to be applied commercially must have certain definite mathematical limits, to permit of them being adjusted to suit special requirements, therefore it is necessary that we consider how we can readily define these limits.

Let us therefore consider several of the units we shall have to employ.

Electrical Units

The practical system of electrical units is based on the C. G. S. (Centigrade, Gramme, Second) electro-magnetic system.

The absolute or C. G. S. unit of Cursent is a current which when flowing in a conductor in the form of a circle of 1 cm radius, produces a magnet force of 2 x 3-1416 units at the centre of the circle.

When a unit current has been allowed to flow in a circuit for 1 second, a positive unit electric charge or quantity, or unit quantity of electricity, is said to have passed round the circuit, in the direction of the current flow.

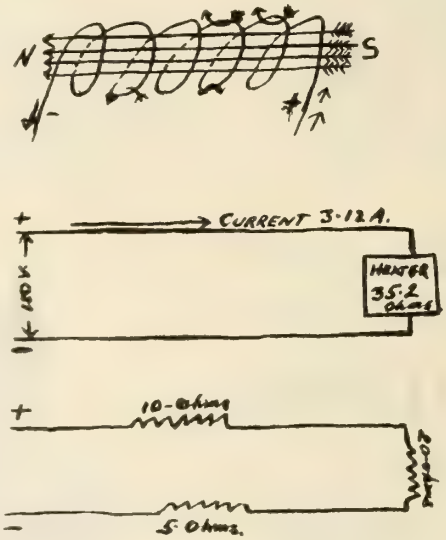
The C. G. S. system of units are not convenient for practical use, being either too small or too large; therefore the following practical system was evolved.

The practical unit of Current is the Ampere, and is equal to 1/10 of the C. G. S. unit.

The practical unit of Quantity is the Coulomb or Ampere-Second and is equal to 1/10 of the C. G. S. unit.

The practical unit of Pressure is the Volt, and is equal to 10^8 C. G. S. units.

The practical unit of Power (volt-



Figs. 1, 2 and 3.

ampere) is the Watt, equal to 10^7 C. G. S. units.

The practical unit of electrical energy is the Joule or Watt-Second and is equal to 10^7 C. G. S. units.

The practical unit of Resistance is the Ohm, and is equal to 10^9 C. G. S. units.

It will now be observed that in every circuit along which current flows, there are always Voltage, Amperage, Resistance, and surrounding the wire a magnetic field. (In an Alternating Current-Circuit several other units enter into our calculations. These will be dealt with in subsequent chapters).

Consider the voltage as exerting a pressure forcing the Ampere against the opposition of the resistance through the circuit. In overcoming this resistance work is done and heat is generated.

In overcoming the resistance and in the generation of heat many of the Volts are absorbed and lost. Hence the necessity for making a provision for the "loss of voltage" in any circuit, otherwise if it is intended to light an electric bulb the voltage or pressure may be so overcome in the struggle that there will not be enough energy left to make the bulb glow with its normal brilliancy.

Before proceeding further let us get a concrete idea of what these units of Pressure, Current, and Resistance really mean.

Practical Definitions

The Ampere (named after Ampere the French physicist) is the unvarying electric current which, when passed through a solution of Silver Nitrate of a particular strength, deposits Silver at the rate of 0.001118 Gram per second.

The Ohm (named after Ohm, a German physicist) is the electrical resistance offered by a column of Mercury, 106.3 cms. high of a cross sectional area 14,4521 Grams in mass and at the temperature of 32 deg. F.

The Volt (named after Volta, an Italian physicist) is 0.6974 of the electrical pressure between the poles of voltaic cell known as Clarks cell. Taken at a temperature of 15 deg. C.

The German physicist Ohm established the law which was named after him. and is known as Ohm's Law. This law establishes the relationship of Resistance to Pressure and Current in any Direct Current Circuit.

Ohm's Law states that:—

The strength of current is equal to the electro-motive force divided by the resistance.

JOS. W. HAYS

Let Me Help Canadians Learn Combustion

I WILL TRAIN YOU AT HOME IN SPARE TIME

What My Years of Experience Have Proven

My years of experience have proven that the real opportunity for success for the boiler room operator is along the lines of Combustion. The man who knows how to burn coal correctly, how to save fuel, who understands efficient plant management, is on the sure road to success. Employers to-day realize the importance of having men in their employ who understand Combustion, and that is why there is such a great demand for men who have a thorough knowledge of the subject. The field is practically a new one. It is not an overcrowded profession, like most engineering professions. It gives, therefore, a real opportunity to the man who has the ambition and foresight to take it up.

We Have Helped Hundreds in Canada

Through the simple, easy reading plan of the Hays Course in Combustion Engineering and Boiler Room Management, we have helped many Canadians like yourself step ahead. Read in the opposite column what our students say about the progress they have made since enrolling for the Hays Course. Because of the fact that the Course has been written in non-technical, every-day style, it is a simple matter for any man to master without difficulty. My work down in the boiler room has shown me exactly the kind of practical training a man needs for success in this field. If you will do your share, I can assure you that the reading and help which my associates and I have provided will quickly fit you to take advantage of the unquestioned opportunities in this field.

Earn—While You Learn—Spare Time

Only your spare time is needed to follow the Course in accordance with the regular schedule. This is the first time that the boiler room operator has had the opportunity to learn Combustion without spending years of effort through the bitter route of experience, or leaving his employment and attending a resident school. The Course takes you through every phase of Combustion, and has been so prepared that you can use what you learn practically from the very day you enroll. It is a Course that fits in with your every day work. The returns for your efforts are immediate and certain.

Send for Our Big New Free Book

We have just prepared an interesting book entitled "Opportunities for the Combustion Expert." It gives you a more complete view of what is going on in the Combustion field, and of just what the Hays Course offers and the actual results it is accomplishing. You will find many helpful ideas which you may apply in your own work, and considerable information both interesting and useful for any power plant man. It will give you an idea of the spirit back of the Hays Course, and why those of us who have spent our lives in this work of fuel conservation and power plant work Messrs. Abbot, Harrington, Low, Moultrop, Myers, Parr, Rice and myself, have been inspired to give the best we have to make the Hays Course a great success and a ready help for any ambitious man who wishes to perfect his knowledge of Combustion and power plant operation. It is intended, however, only for the ambitious man, the man who is not satisfied to stand still and who has made up his mind that he must make further progress. If you are in that class, fill in the coupon and send it to us today. It is absolutely free.

HAYS SCHOOL OF COMBUSTION
CHICAGO

HAYS STUDENTS IN CANADA WIN SUCCESS

From an Employer

Mr. A. J. Moxon,
Vancouver, B.C.

"I was pleased to learn that Mr. Arthur Francis, Fireman at the Empress Hotel, Victoria, had enrolled to take your Combustion Course, and when I was over there I expressed my appreciation of his action. I realize that such men will be more valuable to the Company. I keep these men in mind so that when promotion comes along they are the ones who will get it."

Mr. Leopold C. LeBas,
Edmonton, Alta.

"It is given in a thorough practical way, just as one meets with in every day practice. I read several books on the subject before I took your Course, but there seemed to be something lacking. But after taking your Course I can grasp the principles quite easily and I think that the investment is well worth while to anyone who wants to be above the ordinary in a knowledge of Combustion."

Mr. H. E. Brennan,
Sudbury, Ont.

"I am enclosing herewith my final examination paper. While I experience a feeling of satisfaction at having completed the Course, I have also a feeling of regret that a very pleasant task has come to an end. I am extremely grateful for the knowledge I have gained from the Course, and can conscientiously recommend all Power Plant Engineers to study it. Mr. Hays has written the text in such a way that nobody could help but understand it, and there is not a 'dry' page throughout the whole of the Course."

Mr. A. W. Mason.
St. Andrews By the Sea, N. B.

"Since taking up your Course I have been the means of creating, erecting and operating a Public Electric Lighting System in this little town, which has never had electric light before. Being an employee of the Canadian Pacific and having to arrange for all this in my spare night time, as you know operating engineers are seven days a week men, you can see that I have not had much time to write out examination questions. I am very glad that I subscribed for it."

This law is expressed in a formula as follows:—

$$\text{resistance} = \frac{\text{voltage}}{\text{current}} \text{ or } R = \frac{E}{I}$$

$$\text{current} = \frac{\text{voltage}}{\text{Resistance}} \text{ or } I = \frac{E}{R}$$

voltage = current x resistance or E = I x R.

It is most important that the power house engineer should thoroughly grasp this law, and learn the formula "off by heart" as it will render all the calculations necessary for the distribution of light and power a comparatively easy matter.

With the object of exercising the application of this formula we will now apply it to several problems that will be frequently encountered in the operation of a power plant.

(Ex. 1.) To find resistance. Voltage and Current given.

An electric heater consumes 10 amps, working on a voltage of 100 volts. What is the resistance of the heater?

$$R = \frac{E}{I} = \frac{100}{10} = 10 \text{ Ohms Resistance.}$$

The heating element of an electric oven for use on a 110 Volt circuit is found to have a resistance of 35.2 ohms.

What current will it take when the current is switched on?

$$\text{Current} = \frac{\text{Voltage}}{\text{Resistance}} = \frac{110}{35.2} = 3.12$$

amperes.

How many volts are required to send a current of 25 Amps through a conductor having a resistance of 15 ohms?

Volts = Current x Resistance = 25 x 15= 375 amps.

A coil of wire 85 yards long, when connected to a 220 volt circuit permits a current of 15 amps to pass.

What is the resistance per foot length of wire?

$$\text{Resistance} = \frac{\text{Volts}}{\text{Current}} = \frac{220}{15} = 14.66$$

85 yards x 3 = 255 feet.

ohms for 85 yards.

∴ 255 feet of the above wire has a Resistance of 14.66 ohms.

What is the resistance of 1 foot?

Obviously this will be $\frac{1}{255}$ of 14.66

$$\frac{1 \times 14.66}{255} = .65 \text{ ohms.}$$

The above are just a few examples of the practical application of Ohm's Law. It is most essential that the student should make himself familiar with the practical application of this law, as by repeated practice he will gradually [illegible] an "electrical sense" so that he [illegible] almost instinctively apply this law whenever he has to employ some form of current consuming device on his plant, and for which he naturally must provide the necessary wiring, etc., and allow for the additional consumption of current.

Whenever the necessity arises for any of these electrical calculations it will be found to considerably simplify matters if a sketch of the proposed circuit is made, as by this means one can visualise just what is required and what is actually going to happen. Furthermore this practice has the advantage of familiarising the student with electrical circuits and the methods of tracing them out. (Fig. 2).

Since the advent of the small storage battery for use in starting the automobile it frequently happens that the battery needs recharging. If there is a source of direct current available it is a simple matter (and less costly than taking it to a battery station) to charge at the plant, but great care must be taken to calculate the amount of resistance necessary to only pass the required current, so that the battery is not damaged by the charging at too high a rate. The application of Ohm's Law will then become an interesting and an economic experiment.

Conductance and Resistance

Naturally all the materials used in electrical work offer resistance to the flow of current, and this resistance varies with each substance. All substances and liquids may be divided into three classes, according to the ease with which the electric current can flow through them. These classes are known as "conductors," "semi-conductors," and "non-conductors." The general name applied to a non-conductor is "insulator."

All the metals and alloys appear to be in the class of conductors, certain fluids such as dilute Sulphuric Acid, Sal-ammoniac, Salt Water, etc., are Semi-Conductors.

Rubber, glass, air, paper, ebonite, mica, etc., are insulators.

The power of conducting electricity is called conductance, whilst the power of resisting the flow of electricity is called resistance.

Conductance and resistance are therefore opposite properties, and are possessed to some degree by all substances. A substance that possesses high resistance, also possess low conductance. If therefore we know the resistance of a substance, we can easily find its conductance.

Silver appears to have the highest conductivity, whilst a special alloy of copper and nickel (used in making resistances) has the lowest.

The conductive power of metals varies with their physical condition (whether they are hard drawn or annealed). Alloys according to the percentages of certain metals composing the alloy.

Copper has a lower conductivity than silver, but on account of its comparative cheapness, ductility, and freedom from oxidation, it is generally used for the cables and wires in most electrical work.

Platinum and iron are almost equal in power of conductance, and have only 1/6 the conductivity of copper. Yet in spite of the fact that platinum is dearer than gold and has such comparative poor conductance, it is used exclusively for leading in the current through the glass of the ordinary electric bulb, and also for the contact tips of electric bells. There are however special reasons for its application. In the first case the co-efficients of expansion of glass and platinum are almost equal; the application in this case prevents any leakage of air into the electric bulb, and in the case of the contact points of the electric bell, etc., on account of its power of withstanding the burning and wearing action of electrical sparking.

Care should therefore be taken to see that an electric bell (especially if for heavy duty) possesses platinum contact tips.

The enormous difference between all insulators and conductors can only be appreciated when we compare one of the best and one of the inferior insulators with a conductor such as copper.

According to Ayrton and Mather, "Micanite has a resistivity 2,960 trillion times greater than copper, whilst slate is some 52,000 billion times greater."

The subject of insulators is a very highly technical one, and is only briefly touched upon by the author, as it is necessary that the power house engineer should keep the subject in mind, especially if circuits have to be run in damp places or where steam or chemical fumes are frequently escaping into the air. It should be also borne in mind that the greater the pressure in the circuit, the higher must be the resistance of the insulator employed.

The resistance of a wire depends upon four things:=

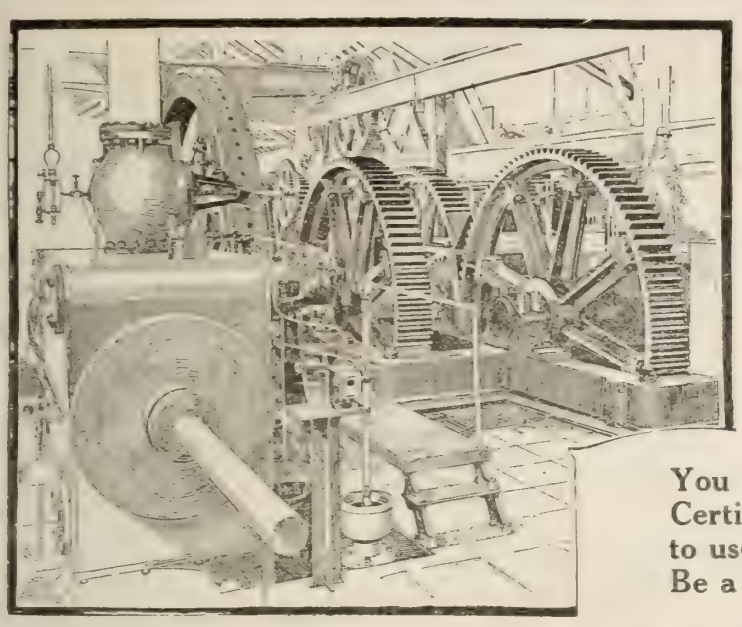
(1) The kind of metal or alloy.
(2) Its Length.
(3) Its cross sectional area.
(4) Its temperature.

The resistance of a given piece of wire (neglecting temperature) is directly proportional to its length, and inversely proportional to its cross sectional area.

Resistance is generally expressed in ohms, but in cases of very high resistance, such as are found in all insulating materials, it is expressed in megohms, a megohm being one million ohms. The Greek letter Ω (capital omega) is the symbol always used to represent megohms, whilst the small omega is frequently used to represent ohms. Very low resistances are expressed in microhms, this being one millionth of an ohm.

As the number of ohms resistance of any length of wire varies in an inverse

YOU Can be a CHIEF ENGINEER

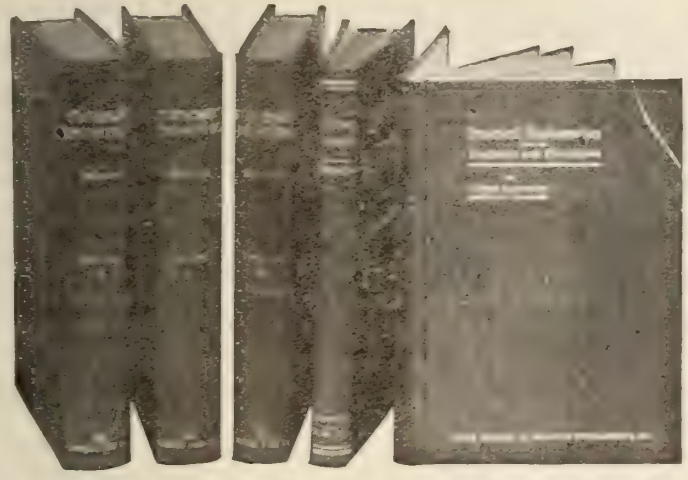


YOUR CERTIFICATE

You don't have to be told what this Certificate will mean to you—a chance to use your head instead of your body. Be a Trained Man!

Give us a chance to show you how to get this Certificate and be a CHIEF ENGINEER

COMPLETE COURSE IN STATIONARY ENGINEERING



covering every branch of power plant work, including Steam Engineering, Practical Mathematics, Electric Wiring and Mechanical Refrigeration. The Course has been prepared by a staff of experts working under the personal supervision of Joseph G. Branch, B. S. M. E., for many years Chief Engineer of the City of St. Louis and head of the Examining Board of Engineers for that City. Although complete in every detail, the Course is written so simply and clearly that **anyone can understand it.** No useless theory—but all the straight facts you need to pass the Engineer's Examinations and become a Chief Engineer.

You Get All These Books at Once FREE

Complete Instructions—36 Lessons

with Examination Questions on each Lesson
Just what you must know

Special Offer—Mail Coupon Quick

The price of the course is extremely low and just now we are making a **special limited offer** to those who reply to this advertisement. This remarkable offer reduces the cost of the complete course to a very low figure. You will be astonished to find how little this tremendously valuable training will cost you. Mail coupon at once for full particulars and special monthly terms.

Joseph G. Branch Institute of Engineering,
JB-4 Branch Building,
3917 Grand Blvd., Chicago.

Without obligation, please send me information how to get a Stationary Engineer's Certificate and full information about your course and Special Terms.

Kingsbury Thrust Bearings

Made in Canada

Our pivoted-block Thrust Bearings are a complete solution of all thrust-bearing problems in hydro-electric units, steam turbines, ships' propeller shafts, centrifugal pumps, and similar work involving heavy loads and high or low speed.

Maximum Durability and Reliability.
Lowest possible Friction.
No limit to loads or speeds.
Protected by numerous Canadian Patents. Complete manufacturing facilities in Canada, insuring prompt deliveries and service.
Send for Catalogue.

ratio with its cross-section, it is important that this point be well understood, otherwise in choosing the size of a cable for transmission of electric power, many thousands of dollars may be lost in the power wasted in the cable.

Area and Diameter

Sectional area and diameter are not directly proportional to each other. A wire with twice the diameter of another has more than twice the sectional area, in fact it will have four times as much. If the diameter is 3 times as great the sectional area will be 9 times. In other words the sectional area is proportional to the square of the diameter. Therefore, if the diameter be doubled, the sectional area will be 4 times as great.

Example:—

To find the cross-sectional area of a conductor given its diameter, and sectional area of a conductor of different diameter.

If a wire has a cross sectional area of .00181 sq. in. what will be the area of a cross-section of a wire whose diameter is 2.5 times as great?

In this example remember that the increase of sectional area will be proportional to the square of the increase of diameter. Thus denoting the diameter of the first wire by 1, and the sectional area to be found by x we have the following proportion:

$$x : .00181 :: (2.5)^2 : 1$$

$$\frac{x}{.00181} = \frac{2.5 \times 2.5}{1}$$

$$x = .00181 \times 6.25$$

$$= .00113 \text{ sq. in.}$$

It is often necessary to find the sectional area of a wire in sq. in. This sectional area is generally termed its effective area, because it is made up of numbers of separate strands of wire, the area of each separate wire only has to be considered. These strands are formed in a circle, we cannot measure the area of each separate strand, so we take the total diameter of the complete circle of wires, square the diameter and then multiply it by .7854 and the result is the area in sq. in. Let D stand for diameter, then—

The sectional area of a wire is $.7854 \times D^2$

Frequently the diameter is expressed in mils, instead of fractions of an inch. One mil is a thousandth part of an inch. (.001) In such cases the sectional area is expressed in circular mils.

Example:—

Find sectional area of a wire whose diameter is 180 mils.

$$180 \text{ Mils} = .18 \text{ in.}$$

$$\text{Sectional area} = .7854 \times (.18)^2$$

$$= .7854 \times .0324$$

$$= .0254 \text{ sq. in.}$$

In all electrical circuits there are various forms of resistance, and it is frequently necessary to find out the total amount of resistance in a given circuit. There are only two ways in which resistances are introduced into the circuit and they are known as series and parallel.

Resistances in Series

The total amount of resistance in a circuit when connected in "series" is the sum of each separate resistance added together.

In Fig. 3 there are three resistances in series having values respectively of 10 ohms, 20 ohms, and 5 ohms. The total resistance therefore is 10+20+5=35 ohms.

Resistances in Parallel

The calculation of resistances in parallel is not quite such a simple matter, except in the case where each of the resistances is of equal value such as a number of similar electric bulbs.

If two similar-sized electric bulbs are connected in parallel the total resistance of the circuit is reduced one-half, if 3 lamps are used it is reduced one-third, etc.

Let the equal number of resistances be denoted by n, and let r be the value of the resistance of one of them, the combined resistance will be shown by the equation.

$$\text{Total Resistance} = \frac{R}{N}$$

Should each of the resistances in parallel vary in resistance, then the total resistance in the circuit is a much more complicated number to calculate.

Conferences have recently been held between representatives of the Bureau of Mines, and the Navy Department concerning the coal developments in the Bering River field of Alaska. The suitability of the coal for navy use and the possible application of the Trent process in treatment of the coal were discussed. Studies have been made regarding the application of this process to assist coal mines producing coal with much impurity in Oregon, Washington and Alaska.

The city council of Montreal, Quebec, plan waterworks improvement for the coming year to the extent of $700,000.

The Peck Carrier

The Answer to Your Coal and Ashes Handling Problem

ONE reliable unit for both coal and ashes, having lower operating, maintenance, power and labor costs than any other type of equipment.

Twenty years of actual operation have proved that the expense of handling ashes in addition to coal is negligible.

You seldom duplicate coal and ashes equipment as you do other power plant units—therefore choose a reliable make and type. Handling both coal and ashes is "play" for this machine.

The Peck Carrier has conveyed and elevated highly abrasive red hot clinker more than fifteen years continuously, twenty-four hours per day.

Peck Carriers installed more than twenty years ago are in daily service today and are still good for many more years.

Why install additional units to handle your ashes, which is approximately 15% amount of coal? Why not choose a proven type of equipment? Why experiment?

We also make:

- Track Hoppers
- Coal Crushers
- Coal Bunkers
- Weigh Larries
- Gates and Chutes
- Drag Scrapers
- Skip Hoists
- Portable Conveyors
- Traveling Water Screens
- Locomotive Cranes
- Electric Hoists

Let our engineers present facts and assist you. Catalog No. 220 on request.

Economy Says "Put a Steam Trap wherever One is Needed!"

The high cost of ordinary steam traps is responsible for an annual steam loss aggregating hundreds of thousands of dollars. When traps run into big money you buy fewer of them and leave untrapped many points that should be protected. Valuable heat units are thus wasted.

Give your steam lines a sufficient number of traps to take care of the condensate as it forms and you will save money. The solution lies in the moderate-priced Steam Trap Sarco.

The price you pay for a single trap of the "bucket" or "float" type buys three Sarcos. Because of its small size and simple mechanism, the Sarco can be manufactured at low cost and sold at a corresponding figure.

Think what it would mean to be able to drain your lines at many points, or to drain individual heating units, instead of using one or two traps on the entire line!

And besides saving money for you in this way the Sarco also saves in maintenance cost and installation expense. Having but one moving part, the Sarco doesn't get out of order, doesn't require expensive repairs, doesn't balk and interfere with production. And it can be placed anywhere in the lines at any angle. No pit digging or platform building required

Our 30-day free trial offer enables you to give the Sarco a tryout at our expense. Write today for Booklet H-22.

Steam trap SARCO

"Pop Off" Steam Carries Ashes Away

"Into the hole and away they go" describes ash removal with a Green Steam Jet System. At the Kewanee Boiler Co., they use "Pop off" waste steam to do the work.

Write to Dept. X for descriptive literature.

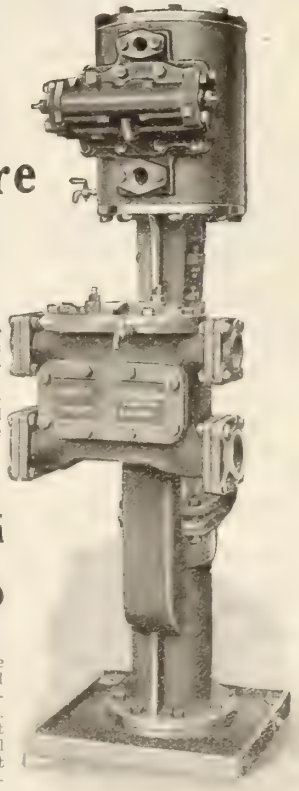
Perfect High Pressure Service



Handling high temperature water at high steam pressures so that there is minimum leakage; minimum attention required; minimum wear on the cylinders—might well be termed perfect service. At any rate this is the way the

HEPBURN Patent Vertical RAM PUMP

serves its many users. There are no Tappets or Levers and Simplicity Dominates the construction. All parts accessible. It runs full stroke even at slowest speed. Occupies small floor space. Ask us also about Engines, Winches, Cranes, Castings and Forgings.

EQUIPMENT

For Sale—Steam Plants

1—Complete plant, consisting of two 72" x 18' boilers with tandem compound Corliss Engine, belt, etc., complete.
1—plant consisting of 72" x 18' boiler with 100 H.P. automatic engine complete
Box No. 27122 P2H

WE BUY IDLE EQUIPMENT OR MACHinery; call or write, mentioning Power House. H. W. Petrie, Ltd. Toronto.

MACHINERY FOR RENTAL — WE WILL rent by the month motors, hoists or contractors' plant of any description. Apply, mentioning Power House, H. W. Petrie, Limited, Toronto.

ELECTRIC MOTORS—NEW AND SECONDhand; electric machinery repaired; we also buy motors. Apply, mentioning Power House, The Electrical Engineering Co., 122 Wellington West, Toronto.

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 100.

FOR SALE—STEAM PLANTS—1. COMPLETE plant consisting of two-72 in. x 16 ft. boilers with tandem compound Corliss Engine, belt etc., complete. — 2. Plant consisting of 72 in. x 18 ft. boiler with 100 H.P. automatic engine complete. Box No. 27122, Power House. P2H

FOR SALE—45 K.W. Edison D.C. 125 V. Dynamo, 1050 R.P.M., with rheostat and spare armature. In perfect condition and can be seen running up to about end of January. Board of Trade Building, Montreal. Price $250. Apply Superintendent.

FOR SALE — FORTY HORSE-POWER VERtical Boiler 120-lb., steam, Ontario inspection, 129-2" tubes 5' 9" long, 74 of them new. Complete with grates, smoke stack and cast iron base. $500.00 F. O. B. Port Arthur.
Return Tubular Boiler 72" x 18' for 115-lb. steam, Ontario inspection, 84-3½" tubes, straight seams, triple rivetted butt joint. This boiler with full flush front and doors, arch-plates, soot doors, but no grates or fittings, for $900.00 F. O. B. Port Arthur. Port Arthur Boiler Works (p1lh)

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS WANTED

ENGINEER—HOLDING ONTARIO CERTIFIcate, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821, Power House. p.2.h.

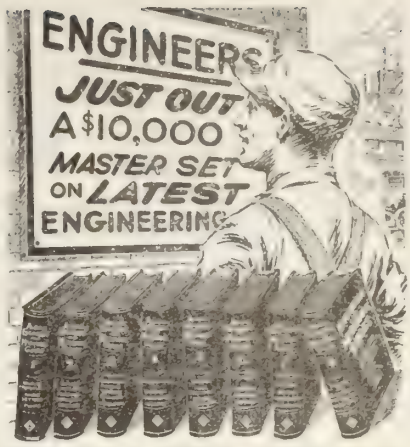
INSTRUCTION BY CORRESPONDENCE FOR First and Second Class Certificates, any province, stationary or marine. Terms and particulars on application. Box 13921, Power House. Ph2

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House, P2H

STATIONARY ENGINEER—SECOND CLASS, requires position, ten years' experience of steam generation, refrigeration, cold storage and electric generation, thoroughly experienced with heating systems and hydraulics and all classes of stationary engines, used to large plants, good references. Apply to Box 5122. P.3H.

STATIONARY ENGINEER DESIRES POSItion as engineer or fireman. Holds second class certificate, 20 years experience. Apply to Box 151121, Power House.

ENGINEER DESIRES POSITION IN POWER plant, experienced with oil burners, holding 3rd class papers. Box 24921 Power House. p.h.



Every Engineer, Mechanic and Electrical Worker will welcome this new material. It will help your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

HINTS TO BUYERS

'Bishop's Adamant' Gauge Glasses

Will resist all Steam Pressure and Variations of Temperature.

REFLEX GAUGE GLASSES

Annealed and Hardened for
LOCOMOTIVES, STEAM WAGONS, MARINE AND STATIONARY BOILERS.

Adamite Gauge Glass Rings. Glass Tubes and Rod

S. & C. BISHOP & CO., St. Helens, Lancashire.

The Simplest and best cleaner on the market is

PILLEY'S

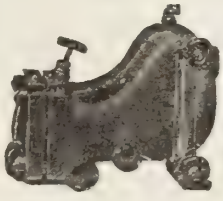
Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.
Manufactured by
PILLEY PACKING AND FLUE BRUSH MFG. CO.
623 South Third Street - - - St. Louis, Mo.
Eastern Office: 71 Fulton St., New York.

GODFREY CONVEYORS
Save Time, Labor and Money

In unloading cars and handling coal, coke, ashes, sand, gravel and similar materials.

Send for descriptive catalogue No. B-1.

M. A. KENNEDY, Limited
106-110 Richmond St. West, Toronto, Canada.
GODFREY CONVEYOR COMPANY
124-147 Thirteenth St. - Elkhart, Indiana, U.S.A.



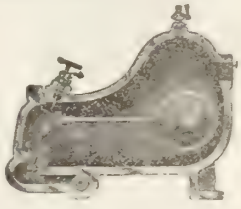
McDaniel Improved STEAM TRAP

FOR HIGH OR LOW PRESSURE

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

May We Send One for Trial?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.



Send for Catalogue

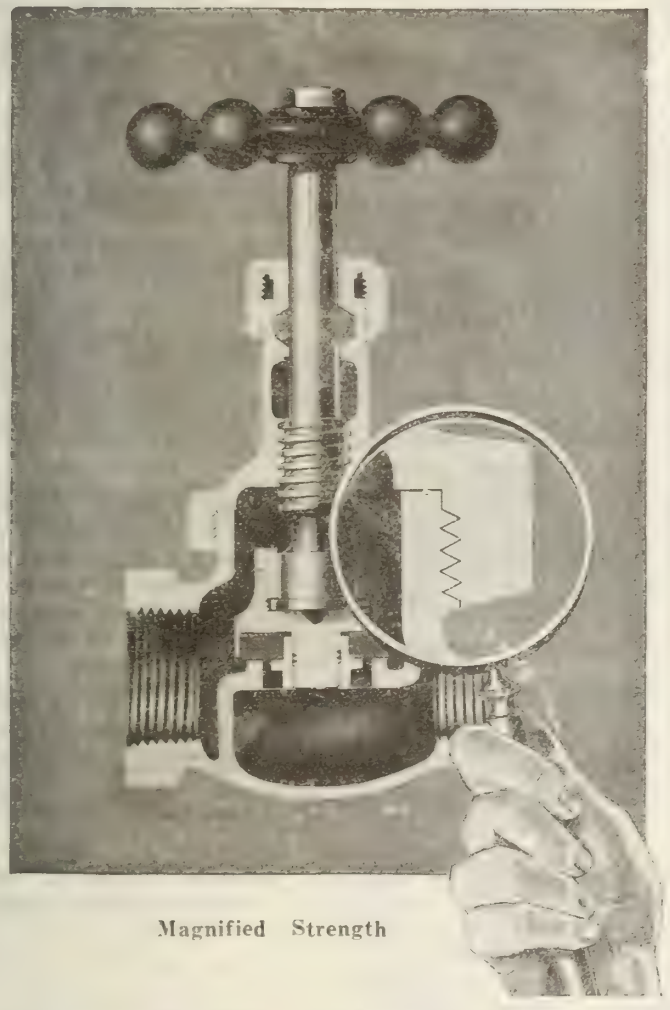
PENBERTHY

MARK.

BRASS COMPODISK VALVES



Magnified Strength

A GLANCE AT THE ILLUSTRATION WILL INTEREST EVERY ENGINEER.

Study it and you will agree that a better valve would be hard to design.

There are no weak points—the distribution of Metal is perfect—

THE EXTERNAL THREAD CONSTRUCTION

makes it strong, practical and safe.

A Better Valve at a Reasonable Price

Modernize Your Plant---

Apply Elesco Superheaters---Save Fuel---gain additional boiler capacity

The Elesco Superheater is a real modernizing factor. Old plants, Elesco-equipped, gain an economy and effectiveness in operation which compare favorably with the most modern plants.

Elesco Superheaters save from 10 to 20% of the fuel burned under a saturated boiler.

At one fifth the cost of new boilers, Elesco Superheaters add 25% to existing boiler capacity.

The outlay involved is soon returned in fuel savings.

As a first step in your investigation of Elesco Superheaters and their possibilities in your plant, send for Bulletin NT-7.

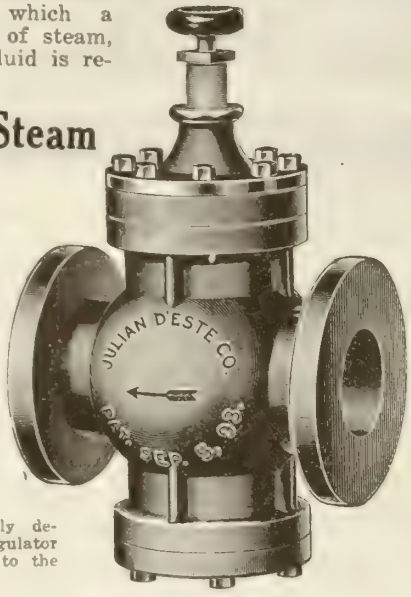
CURTIS Engineering Specialties

Universality!

For universal application to all the varied and various conditions under which a reduced pressure of steam, water or other fluid is required the

Improved Steam Pressure Regulator



has no equal.
It is compact and self-contained, without levers, weights or projections.
No glands or packing; no drip for leak of steam or water. Suitable for any boiler pressure; made entirely of metal; is a lock valve, very simple and sensitive.
Send for leaflet fully descriptive of this Regulator (contains price list) to the manufacturers.

Canadian funds are accepted at par at Montreal.

What Are We Waiting For?.....

HERE we have a nation of people accustomed to work—with as high a consuming capacity as any in the world—with ample money resources—with new materials that are the envy of the world. What on earth are we waiting for—what more do we want to have done for us for business to be "good" again?

Let's each do one little thing now—and see the mighty change it will make—buy anything we NEED and buy it now. If your plant needs new Boilers, buy them NOW. We make all types and sizes. Our workmanship is excellent, our prices low.

Files Hand Stokers Getting Results

PANTHER RUBBER COMPANY, LIMITED

GENERAL OFFICES AND FACTORIES
SHERBROOKE, QUE.

SHERBROOKE, CANADA September 23, 1921.

The Waterous Engine Works Co. Ltd.,
Brantford, Ont.

Gentlemen:

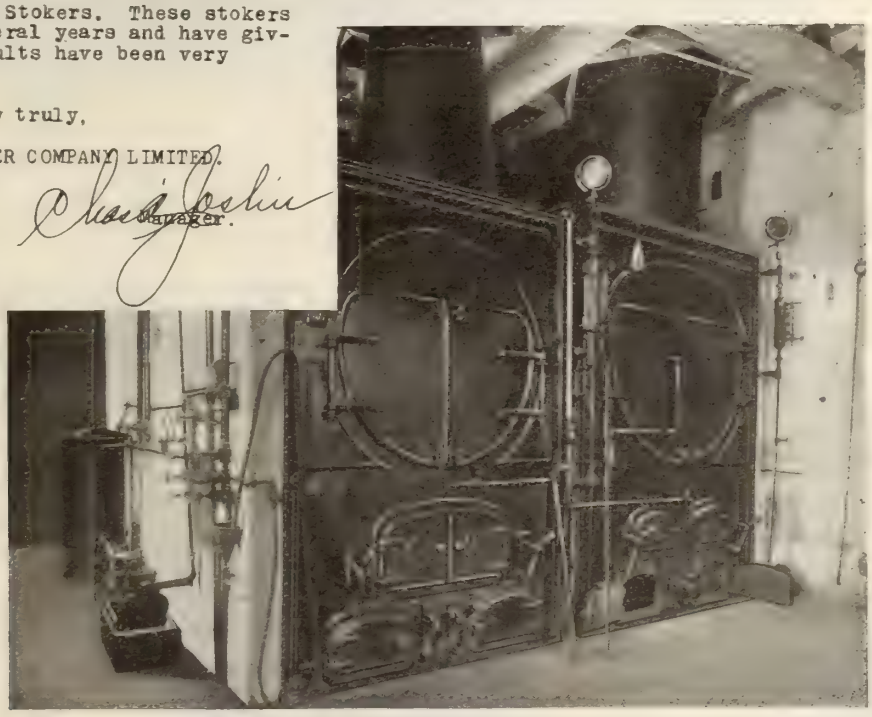
In reply to your letter of the 8th instant we have in our plant the Files Stokers. These stokers have been in operation for several years and have given excellent service. The results have been very satisfactory.

Yours very truly,

PANTHER RUBBER COMPANY LIMITED.

Manager.

CAJ/RMK



It is the uniform excellent service and general satisfaction that have caused progressive men to select **Files Stokers.** These are typical of the more complete data we have compiled:

One installation (3,600 H.P.) saved enough coal to pay for their stoker investment in five months.

A Files installation operated for five months continuously at an average rating of 223%—doubling their steam output.

Files stokers increased efficiency of one plant sufficiently high to warrant discontinuance of two out of eight boilers.

Here is a ready explanation of these achievements:—

1. **Complete volatilization of green coal, causing intensified combustion and smoke dissemination.**
2. **Correct distribution and proper proportion of air according to load carried**
3. **Fuel bed continuously kept clean, uniform and rich.**

Given the opportunity we will be glad to present these facts for your complete satisfaction.

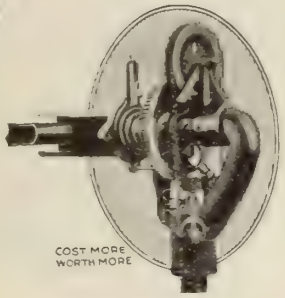
Greater Cleanliness of Boilers Assured

DIAMOND
VALV-IN-HEAD
SOOT BLOWERS



A MARKED advantage in the use of the Diamond Valv-in-Head soot blower is the increase in effective pressure in the blower element. This is due to two factors. First—the valve offers practically a straight passage to the steam, whereas in other systems the steam must take two right angle turns through the globe valve, which causes an appreciable drop in pressure. Second—the Valv-in-Head system requires about half the quantity of pipe, valves and fittings used with other blowers, and on this account the pressure drop from source of steam to blower element is very much less.

The outstanding advantage of this increase in effective pressure is, of course, the increase in cleaning efficiency of the steam jets. With increased velocity the range of the steam jets is considerably greater and the boiler is more thoroughly cleaned in all respects.

As boilers are only effectively cleaned when the steam jets play on the tubes for a pre-determined period of time, a third and extremely important factor in insuring greater effectiveness is the use of the Valv-in-Head of reduction gearing which regulates the speed of the blower element so that all tubes are equally and thoroughly cleaned.

Greater cleanliness is only one of eleven important advantages of Diamond Valv-in-Head soot blowers. Why not let us tell you about the others?

Every boiler needs a mechanical soot blower and you will save money by buying the best. Diamond Valv-in-Head blowers are adapted to all types of water tube boilers. On request our Engineer will go over your existing soot blower installation and advise whether it can profitably be replaced with the Diamond Valv-in-Head system. Ask for your copy of Bulletin 287 describing the new soot blower.

SOOT BLOWERS - SAVE 4 to 8% FUEL

More Than Ten Years' Service

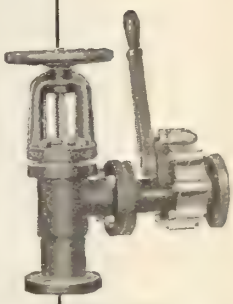
Not One Cent for Repairs

The two Yarway Seatless Blow-Off Valves shown below are in the plant of the Riverside Highland Water Co., Colton, Cal.

These valves have been in continuous service since their installation in February, 1912. One has never been repacked; the other was repacked once.

The packing used was furnished with the original order, so these two valves have not cost one cent for repairs in ten years of service. Recently, they were reported both absolutely tight.

Records like this indicate one reason why so many careful, economical operators prefer the Yarway Seatless Blow-Off Valve. The whole story is told in Booklet B-410—awaiting your request.



If you require two valves on the blow-off line, remember this: the Yarway Seatless and Yarway Double Tightening Valves in tandem give blow-off security and satisfaction.

New Truths and Old Fallacies

WEARING QUALITY - Continued

The writer witnessed the remetalling, with Magnolia, of a large quarter-box engine bearing about 18" x 22". Owing to its difficult location, which occasioned considerable loss of time in removing and replacing, besides the time spent by the pattern makers' and machinists' work, it took practically ten or twelve hours to complete this job. In the meantime the mill was shut down, at heavy loss of production and a dozen or more men were engaged in this work.

Imagine using on this bearing any metal of unknown or doubtful quality for the purpose of effecting a saving in cost. It would have been unpardonable to have jeopardized such an important interest for such a trifling consideration.

By using Magnolia, engineers and mechanics are practically relieved of all censure in case of trouble with the bearings because it is the recognized standard throughout the mechanical world, and, therefore, its use implies no lack of judgment or forethought. We are fixed unalterably in our belief that it is true economy to use Magnolia on bearings of all classes however light and unimportant the service, as the saving in the long run in power, oil, wear, etc., will far exceed the difference in cost between Magnolia and cheaper grades of metals.

In a case brought to our notice, a line shafting babbitted with Magnolia "was the only thing about the factory that had withstood the ravages of time" after long service. The computation of the saving in this instance in comparison with what a cheaper metal would have cost, if such computation were possible, would be an eye-opener.

Riley Stokers---Union Central Life Insurance Bldg.

CINCINNATI, OHIO

The Union Central Life Insurance Building is the tallest office building west of New York City. It towers 495 ft. above the street level and contains 8 acres of floor space.

Speaking of the

RILEY UNDERFEED STOKERS

installed here the Manager of this building states:

"The Riley stokers installed in our boiler room have been giving us complete satisfaction, and have been in almost continuous operation since their installation."

Riley Stokers are particularly adapted where elimination of smoke is a necessity. The **moving grates** keep the fuel bed even, active and porous, allowing an intimate mixture with air at all times. The hydrocarbon gases after being distilled in the retorts pass up through an active body of burning coke, then through the fire zone, passing off as invisible, completely burned gases.

Ask for our Catalog H-3, describing the Riley Underfeed Stoker in full.

The Sanford Riley Stoker Company is now prepared to equip new Riley Stokers with coal agitators licensed under the Negus-Tiffany patents.

Now is the Time for Repairs

Many a Factory and Mill can confidently look forward to an early date when their plant will be running full time. Every factory should be gone over and needed repairs to BELTING attended to now. It would be disastrous to stop at a rush time and it would be foolish to run the risk of a hold-up through neglect.

Look Over the Belting

To make sure your wheels will never stop turning through the breakdown of Belts, equip every machine with

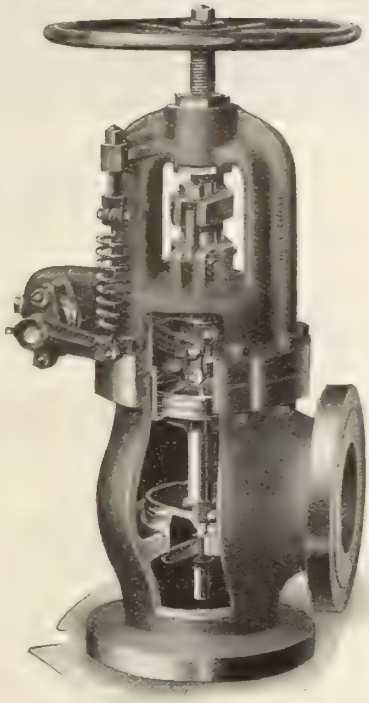
Safety Non-Return Valves



Iron Body, Bronze Mounted

Angle Valve, Fig. 700
Globe Valve, Fig. 374

Cast Steel

Angle Valve, Fig. 1282
Globe Valve, Fig. 1281

LUNKENHEIMER SAFETY NON-RETURN VALVES have proved their reliability in service, automatically closing and instantaneously cutting out a boiler connected in battery when the pressure within the boiler, through accident or otherwise, suddenly drops below that in the header. Their action facilitates the continued operation of the other boilers and enables the plant operatives to pursue their duties in safety.

Workmen who may have occasion to enter a dead boiler for cleaning or repairs are likewise protected, as these Valves cannot be opened by hand.

Sizes 3 to 10 inches, in Iron Body Bronze Mounted for pressures up to 250 pounds and in Cast Steel Monel Mounted for pressures up to 350 pounds and temperature to 800°F.

For Safety, Reliability and Efficiency specify LUNKENHEIMER SAFETY NON-RETURN VALVES and insist on their installation.

Distributors of LUNKENHEIMER Products situated in every commercial center.

Mechanical Perfection Means Profit Protection

The reasons why Bowser Oil Handling Equipment stores oil economically and safely are shown in the above drawing of the Fig. 64.

The Tank, being riveted and soldered from inside, is absolutely and permanently leak proof.

The Pump is rapid in action and equipped with mechanical measuring stops. A liquid test before shipping assures accuracy.

A permanently tight tank avoids loss from leakage—it prevents contamination of oil, and keeps the oil room clean. Thus cleanliness is stimulated on the part of the employee.

The Piston-Type Measuring Pump quickly and accurately delivers any desired quantity directly into the receptacle. This prevents overflow of oilers—saves time and oil.

Does *Your* Covering Look like This?

IT SHOULD, if your Nonpareil Cork Covering has been put on right and *cared for properly*. Nothing will more surely repay you than to go over your lines now and make any needed repairs before spring.

See that there are no loose or broken wires and that all joints are tightly sealed. Open joints not only lose refrigeration, but allow frost to form, which will eventually destroy the covering. To preserve the mineral rubber finish on the outer surface, Nonpareil Cork Covering should have a coat of asphaltic paint once a year. Such repairs are easily and cheaply made and there is no better time than now, when you can have your lines free from frost.

Your Nonpareil Cork Covering is too good an investment to neglect. Every year, it pays back its cost in refrigeration saved—a 100% return which reasonable care will preserve for years to come.

Nonpareil Waterproof Cement, Seam Filler, Brine Putty, Copper-clad Wire and Asphaltic Paint will be supplied on order.

"An ounce of prevention is worth a pound of cure."

Write for the 64-page book, "Nonpareil Cork Covering." It is sent free of charge and is a treasury of information on cold pipe losses and how to stop them.

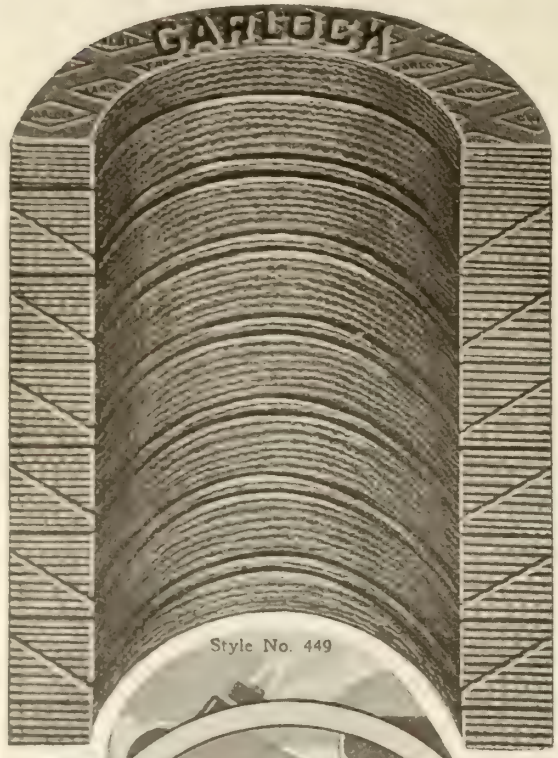
FROM ARCTIC COLD TO SUPERHEAT



To withstand the wide variations of temperature and severe conditions of ice machine service, a special ammonia packing is necessary.

A packing failure in a plant having reserve compressors might merely result in ammonia loss, while in a smaller plant running at "peak load"—a shut down due to inferior packing could result in a loss far exceeding the cost of a special high-grade packing. Garlock Style No. 449 is a packing set specially designed for service on ammonia compressor rods. Years of successful experience have proven this packing best suited to the work.

Packed in dust-proof cartons—extra sets can be kept in reserve—always in perfect condition for emergency use.

Two ways to buy less sheet packing—

based upon actual practice in thousands of plants

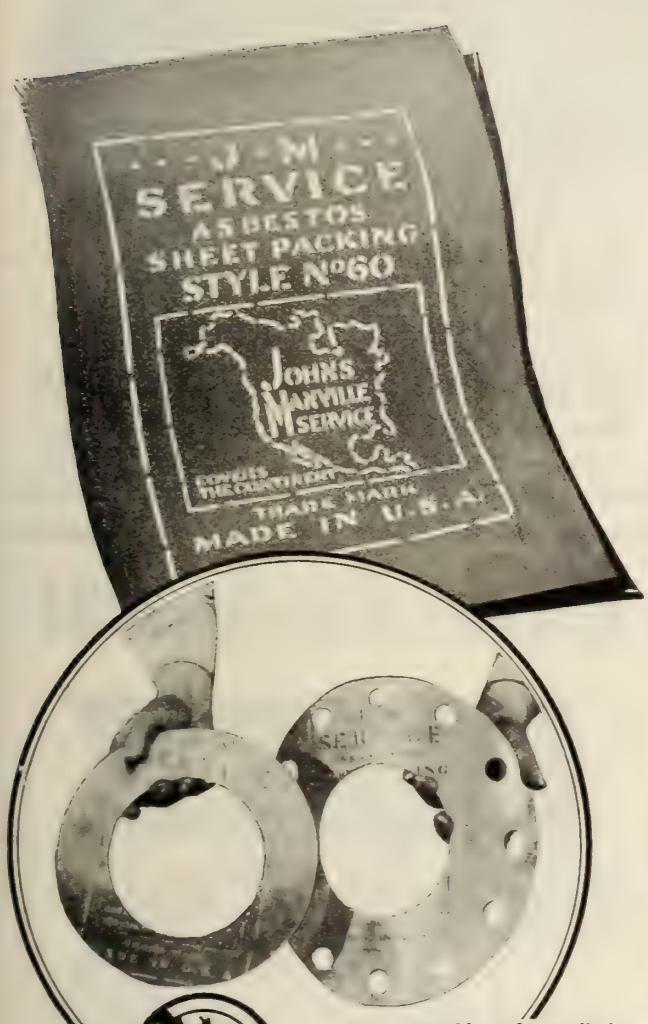
1st. Cut your gasket smaller. The ring gasket pictured at the left has an advantage over the full cut gasket in addition to the fact that it takes much less material. It makes a tighter, better joint.

This is true because the ring gasket allows a greater and more uniform pressure to be brought against the gasket—more pounds per square inch of packing than is possible with a full cut gasket.

2nd. Always use Johns-Manville Service Sheet. It answers practically every sheet packing requirement. This one packing, made of durable Asbestos fibre and heat-resisting compounds, is taking the place of several separate packings for oil, steam, water, chemicals and other varied conditions.

Use Service Sheet and you reduce investment in packing and save storage space. You save the item of packing deterioration on storeroom shelves. You save on waste too, because after a gasket is cut the overage will last indefinitely.

So then, the small ring gasket makes possible more gaskets from the same material. Johns-Manville Service Sheet, the durable, all-around packing, means cheaper packing in the long run and better packing from the start.



Read how the smaller gasket, besides saving material, makes a better joint.

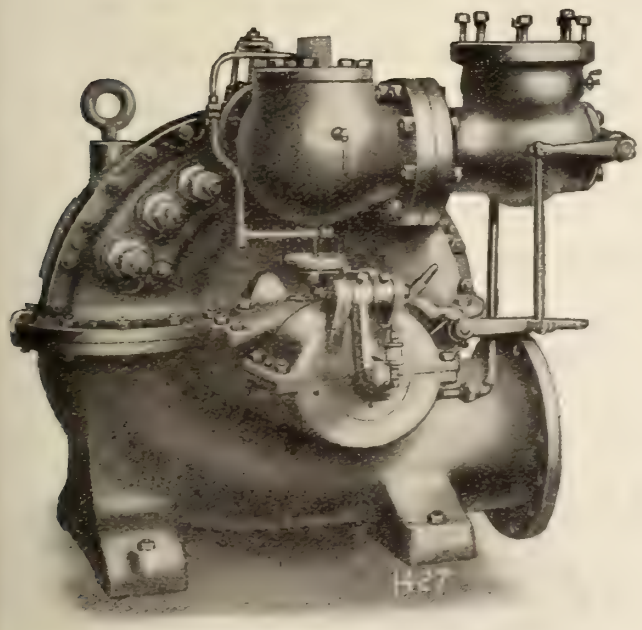
Keep High-Temperature Steam Away From Bearings



THE new DE LAVAL VELOCITY-STAGE TURBINE meets the requirements of modern steam plants using high pressure superheated steam. The cast-steel steam chest is in the upper part of the casing, away from the bearings and their supports. Only low-pressure, low-temperature steam enters the wheel chamber. Hand-controlled nozzles provide for maintaining efficiency with varying load and steam pressure. The speed is controlled by a powerful and accurate governor, besides which there is an entirely independent emergency trip with shut-off valve.

De Laval Steam Turbines are built on a limit-gage interchangeable basis in all sizes up to 15,000 H. P. and for all steam conditions.

A New Type of High Efficiency Condenser

How a Condenser Influences the Costs of a Power Plant. The Effects of Velocity on Corrosion a Very Important Item in The Surface Type. Points on Design

By PAUL A. BANCEL

Of the Ingersoll Rand Co., New York, before the American Society of Mechanical Engineers.

THE HEART of a power plant lies in the boiler room, and the most important aspect of the condensing plant is in its relation to boiler-room costs. The choice of a condenser may be said to rest largely on its influence in reducing boiler-room charges. As indicated in Fig. 1, it would pay to run condensing if coal cost nothing; and pay even more, if the boiler feed was poor or expensive, to install the costliest of condensers—the surface type. With pure feedwater there is less fuel loss and boiler-maintenance charges, and, what is of still greater importance, boilers may be driven at higher ratings with consequent further reductions in first costs and fixed charges.

The designer of a power house is in a quandary—flying from boiler evils to condenser evils, and often with hesitancy as to which are the less serious. The problem is one of balancing fixed and operating charges in the boiler room against similar charges in the condensing plant.

Fixed Charges

The fixed charges against a surface-condensing plant depend on—

(a) Vacuum desired, which influences the size and cost of the equipment.

(b) Cost of tube replacement, which depends on amount of tube surface in any particular design and life of the tubes as influenced by water conditions and condenser design.

(c) Power for the auxiliaries, which increases if the cost and fixed charges are reduced.

Vacuum. In Fig. 2 the curve 0-0-0 shows the absolute back pressures at the turbine exhaust which might be expected from a cycle of water temperatures and a certain investment in condenser. Frequently the design of the turbine is such and the water temperatures in the winter are so low that for certain winter periods a vacuum is obtained which is better than can be utilized by the turbine. On the other hand, the temperature of the available water supply for three to six months of the summer is 60 to 80 deg., so that the vacuums obtainable are lower than are desirable for maximum turbine economy. Fig. 1.—Relative First Cost of Steam Power Plant at different vacuums.

in Fig. 2 indicates the range of vacuums by investing more or less money.

As will be seen later, extensive calculations in regard to best investment are apt to be misleading because of the reduction in vacuum which so often occurs due to fouling of the tubes. In such instances all other questions become subordinate to that of maintaining high vacuum continuously, under actual operating conditions. In other cases the decision must rest on the relation of load factor, months of the year having hot water and the fixed charges and operating charges at different vacuums.

Cost of Tube Replacement

This can be set up as a yearly depreciation reserve. The life of a condensing plant might be 20 years, whereas the tube life might be only five. On a 10,000 k.w. turbine this might necessitate the purchase every five years of tubes costing about $10,000. Thus in determining the best vacuum the item of tube renewals may have a preponderating influence. Furthermore, as between two condensers for the same vacuum, one of which requires less tubes than the other, it is manifest that the fewer the tubes the less the fixed charges.

Similarly, the longer the tube life the smaller the fixed charges and cost of power. In one plant the tube life might be five years and in others a great deal more or a great deal less. Tube life depends on the character of the water supply, on the chemical, physical and metallographic properties of the tubes (crystalline structure) and it also depends on the design of the condenser. The latest report of the Corrosion Committee of the Institute of Metals, London, summarizes the types of condenser-tube corrosion, principally general thinning, pitting and apparent dezincification. The fourth and fifth reports of this Corrosion Committee are exhaustive studies of the subject, and among other causes emphasize the effect on corrosion of low velocity and high temperature.

Velocity has a direct effect on corrosion. Low velocity allows the deposit of foreign matter in the tubes which forms obstructions around which the products of corrosion accumulate in concentrated form, with the resultant pitting. High velocity keeps the tubes clean and eliminates this form of corrosion.

High temperature accelerates corrosion of all types and so seriously that a temperature of 95 deg. Fah. is recommended as the maximum. There are three ways of reducing temperatures in order to alleviate corrosion: by increasing the water quantity thus decreasing the overall rise; second, by eliminating hot spots and local overheating of tubes; third, by increasing water velocity or decreasing tube size, thus decreasing the

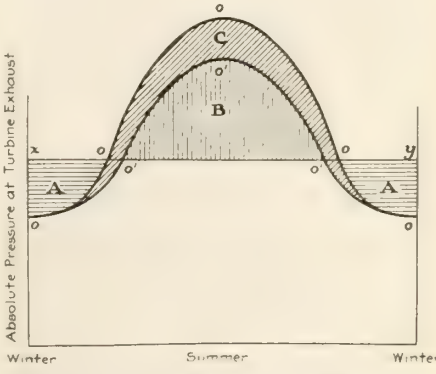

Fig. 2.—Cycle of absolute back pressure of gear line x y, represents highest vacuum or lowest desirable exhaust pressure. Areas AA represent waste in winter, due to excessive vacuum and areas B. & C. waste in summer, due to warm water and insufficient vacuum. Area C represents improvement possible by investing more money.

skin temperature at the tube wall. The first of these needs no comment. As to the second, it is well known that faulty steam distribution causes excessive heating of the water in some tubes counterbalanced by practically no heating of other tubes. Thus in condensers in which the steam distribution is obtained by lanes, the tubes in the path of the steam heat the water rapidly, but they short-circuit the tubes within the banks. The short-circuited tubes are not only wasted surface, but are the cause of the excessive temperatures in the exposed tubes, which consequently corrode rapidly.

The third method of reducing temperature, higher velocity and smaller tube size, may need explanation. It is well known that more heat is transferred for a fixed area of tube surface and fixed conditions of steam temperature and water velocity is increased or tube diameter reduced. The tube acts as though a colder water supply were being used and this is exactly what is happening because the water at the walls is really colder. The metal is therefore colder and can abstract more heat in the same time from steam at the same temperature.

The flow of water in a tube is accompanied by cross-currents and whirls which convey the heat from the walls into the body of the water. In Fig. 3, if thermometers were placed as indicated the temperature readings would follow a curve as shown. Increased velocity reduces the temperature at the walls, making the curve flatter. Similarly, using a smaller tube reduces the temperature at the walls and makes the temperature gradient flatter. The inner skin temperature may be approximated from various experimental results on heat transmission and curves obtained as in Fig. 4, which shows the relation between the water velocity and this inner skin temperature for conditions of constant load (Curve A) and constant vacuum (Curves B and C). In all cases increasing the velocity reduces this temperature.

In a condenser with proper distribution to avoid hot spots, and with suitable velocity and tube diameter to further reduce skin temperature and prevent foreign deposits, a markedly longer life of tubes will be obtained. As will be seen, too, these features of design result in small initial surface requirements, so that there is a twofold reduction in the fixed charges to take care of replacements.

Operating Charges

The principal operating charges on a condensing plant may be grouped as follows:

(a) Reduction of condensate temperature below steam temperature and consequent loss of coal.

(b) Power for operating the auxiliaries.

(c) Reduction of vacuum and increased coal consumption due to scaling and sliming of the tubes.

(d) Cost and time to clean the tubes and cost and time lost due to tube failure

and consequent pollution of the boiler feed.

Reduction or Depression in Condensate Temperature below steam temperature depends on condenser design and temperature of circulating water, being less with warm water and greater with cold water. The water of condensation must fall over successive rows of tubes to reach the bottom and if the steam is not drawn down to the bottom of the condenser, the water will be gradually cooled. The cooler the water and higher the vacuum the greater the proportion of idle surface and the colder the condensate. Even in those condensers, in which numerous short-circuiting lanes are provided for the express purpose of securing penetration of the steam, there is a depression of condensate temperature of 5 to 10 deg. in summer and 10 to 20 deg. in winter. Eleven degrees loss of condensate temperature represents 1 per cent. loss of efficiency and is equivalent to 300 kw. on a 30,000 k.w. machine. In some plants this loss is largely overcome by the installation of preheaters.

Power for Operating the Auxiliaries has already been considered in a sense in the discussion of fixed charges, since the power required for any vacuum is partly dependent on the investment, and may be decreased by increasing the investment and fixed charges. No distinction should be made between the power required for driving condenser auxiliaries and the main power output of the plant, even where the auxiliaries are steam-driven and exhaust to a feed heater. The auxiliary power is a direct charge against the main unit output.

The principal item of power consumption lies in the circulating pump, and this unit is often arranged for variable-speed drive or else is divided into smaller units, so that with cold water or light load the operating charge may be reduced by slowing down or by shutting down one pump. As shown in Fig. 2, an excessive vacuum is obtainable in the winter and the waste of fixed charges can be partially offset by saving on the circulating-pump power.

The best balance of circulating-pump power in summer time for conditions of maximum water temperature and full load must be settled after consideration of all the aspects of the problem. By proportioning the condenser for low water velocities the head on the circulating pump may be made low, and the quantity of water used very low with small power requirement for driving the pump. This saving, however, may be counterbalanced by excessive fixed charges distributed over a relatively small part of the year. Thus suppose the investment were increased $5,000 on a 10,000-k.w. unit, and the circulating-pump power reduced by 50 k.w. The added fixed charges including tube renewals might be $1,000 per year, and if this be charged against the summer months, the rate might be 50 cents to several dollars per hour depending on the number of hours. This would offset 50 k.w. For this reason many plants use two pumps in the summer, working under relatively high heads of 30 to 40 ft.

Low pump power with low water velocities may be offset also by increased operating charges due to low vacuum resulting from fouling. Fig. 5 is similar to Fig. 2, except that a shaded portion D has been added to indicate the range of vacuum in the summer time under actual conditions of fouling of condenser tubes. As much as an inch of vacuum is lost in a week in some cases, and in one extreme instance there is a loss of an inch in two days. It is unfortunate that the loss by fouling is most severe in the summer when it is most difficult to obtain high vacuum. As a reduction of only ¼ in. in vacuum represents a loss of 1½ to 2 per cent. of turbine economy, which may be equivalent to all the auxiliary power, it is readily seen how easily all calculations of exact balance between fixed charges against the condenser and operating charges against the auxiliaries may be disrupted.

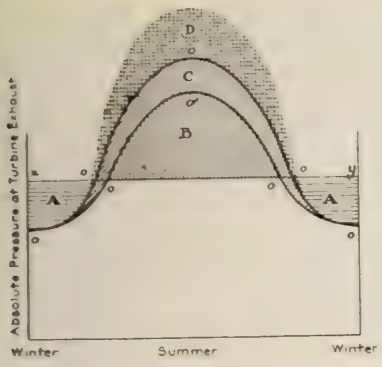
Reduction in Vacuum Due to Tube fouling. The foreign matter that accumulates in condenser tubes may be divided into three classes:

(a) Mechanical deposits, silt and mud.

(b) Scales deposited out of solution.

(c) Slimes or organic growths.

The first of these is of minor influence in reducing vacuum unless water velocities are low indeed. The ability of a stream of water to carry solid substances in suspension increases rapidly with increase of the velocity. However, foreign matter such as silt, may be deposited in the slime coatings which



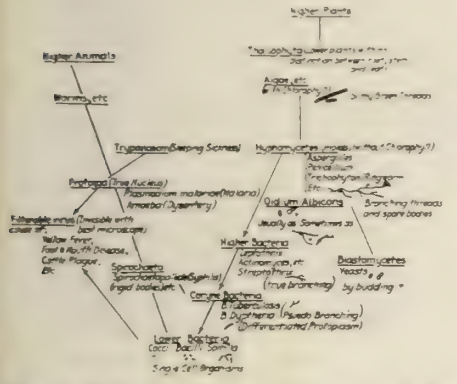


Fig. 5.—Cycle of absolute back pressures at different seasons. Area shows increased back pressure, due to fouling.

Fig. 6.—Forms of life in condenser tube slime.

form a more adherent surface than a clean condenser tube.

The second form of deposits is common with salt water and hard waters carrying scale-forming salts, familiar in impure boiler feedwater. In many cases with cooling towers or spray ponds the source of make-up is a relatively hard water and causes deposits of sludge and scales in the condenser tubes. The commonest ingredients of such water are calcium and magnesium carbonate which are soluble in the presence of carbon dioxide. Heating the water drives off the CO_2 and precipitates the carbonates.

Fig. 7.—Comparison of steam flow in turbine and correctly designed condenser.

The influence of uniform steam distribution, smaller tube size and high water velocity on reducing skin temperatures has already been shown. It is also probable that high velocity has a mechanical effect in reducing the rapidity of such scale formations. In sugar evaporators it is commonly found that the tubes which work actively and therefore contain rapidly rising currents of mixed vapor and juice, scale the least; whereas tubes doing less evaporation foul more heavily.

Where extremely hard waters are encountered it is desirable not only to keep down the temperatures by observing the principles of high skin velocity and activity, but also by using larger quantities of water and smaller overall temperature rise. In this way it is possible as between two condensing plants to reduce the maximum temperature rise of the skin of water in the hottest tubes, 10 or 20 deg., or even more.

Slimes or organic growths are the third form of deposits. Fouling of this character is most severe in the summer time, and is also most severe in hot portions of a condenser with improper steam distribution. Thus, in a condenser with lanes, the tubes in the lanes will be found coated with thick, heavy slime in a short time, whereas tubes in the short-circuited regions will be but slightly fouled. It is probable that these slimes are organic growths occurring under the ideal conditions of warmth and stagnation existing at the inner skin of the tube. A typical sample of condenser-tube slime was taken a short time ago by the author and given to a bacteriologist for analysis. A large number of hyphomycetes were demonstrated. This form of life is classified between bacteria and plants, as shown in Fig. 6. The hyphomycetes grow rapidly as long microscopic threads (Mycelia), which branch rapidly, forming a dense interlacing network in which all other organic and inorganic elements are caught. They grow better in an acid than an alkaline medium. The hyphomycetes are familar to us as molds and fungi and are a form of life just below the algae, which are the green slimes frequently seen in stagnant pools. The algal contain chlorsphyl and require light for their growth, whereas the hyphomycetes grow in the dark. The conditions for rapid growth are moisture, stagnation and a fair warmth. The optimum temperature is between 20 and 40 deg. cent. (68-104 deg. Fah.); when spores are formed they are more resistant to higher temperatures.

There are cases on record of two condensers side by side, one with low velocity the other with high velocity, in which the latter remains cleaner for longer periods. Similarly it is well known that condensers do not lose as much vacuum or have to be cleaned as frequently in the winter as in the summer, and also that those parts of the condenser that are hot foul more rapidly than those where the water is not heated. In one instance a condenser is so large that it is cleaned only part at a time and when this practice was initiated the operating force found that cleaning the two lower quarters and one upper quarter improved the vacuum very slightly, whereas cleaning the last quarter which was exposed to the full activity of the steam brought the vacuum back to normal. In this section, the tubes exposed to steam are so heavily fouled that two men are needed sometimes to push the brushes through. The same arrangement of tubes to prevent local overheating, and the use of high water velocities to reduce inner skin temperatures and increase the activity and counteract stagnation along the inner wall of the tube, may be expected, therefore, to reduce and eliminate the formation of organic slimes. Corrosion, scaling and sliming can all be reduced by correct proportion of a condenser for high activity of water flow and turbulence at the tube wall and uniform steam distribution, factors which in addition permit of a large reduction in the amount of tube surface.

Fouling adds to the operating charges in another way, as there may be a large labor cost for cleaning. The time loss with a unit out of service is also a con-

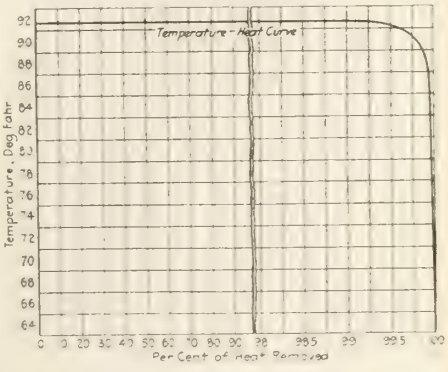

Fig. 9.—Relation between percentage of heat removed from a mixture of steam and air and temperature of the mixture.

Note:—Scale is magnified 40 times at right hand section of chart for the assumed mixture which is a fair average in high vacuum condensers. The temperature starts to fall at 99 per cent.

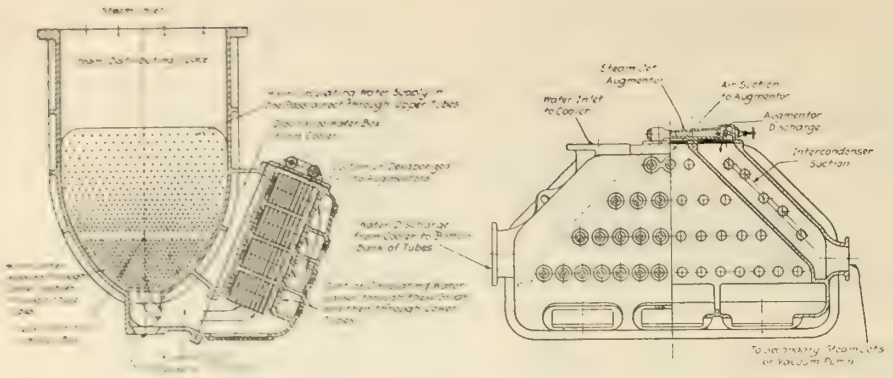

Fig. 10.—Cross section through main condenser and cooler of surface condenser.

siderable item of cost. The charges due to failure of tubes by splitting and corrosion are of a similar nature. The pollution of the condensate and consequent scaling of the boilers from either impure condensate or from raw feedwater adds to the operating charge in the boiler room. The loss of time on the complete power-generating unit required to shut down, locate, and plug the leaking tube adds to the turbine-room operating charges.

Clogging of Tubes. One other loss adding to operating charge is that caused by clogging of tubes by accumulation of miscellaneous solid substances against the tube sheet. This applies only to plants using natural water supplies. With spray ponds the nozzles clog long before the condenser tubes. Clogging can be reduced by proper screening, and the use of flush, well-rounded tube inlets and high water velocities. Low velocities are wanted in the screens, but high velocities and clear inlets into the tubes. The influence of velocity is clearly shown by the tendency in two-pass condensers for the tubes of the return pass to clog with solid matter which originally came through the first pass. This clogging is most noticeable toward the top (where the water is needed most) and is due no doubt to the slow velocities at the top of the return box, which is at the top of the siphon and acts as a skimming tank.

Condenser Design

The design of a surface condenser to conform with the requirements which have been outlined, lies in the proper application of certain well-known principles. The first of these is to keep all of the tubes uniformly hot on the steam side so that the minimum number will be needed because none are wasted. To accomplish this the steam must be free to flow to all the tubes and over all the tubes, with slight loss of pressure and temperature, the condenser being arranged in stages, much as is a turbine, with large flow areas at the exhaust entrance and great distances between rows to avoid sharp bends and pressure loss. Fig. 7 illustrates the analogy.

Of equal importance in keeping all tubes hot is the proper staging to maintain velocities that will sweep the air ahead in the current of steam and the arrangement of tubes in staggered rows so that none is shielded or pocketed. Air left on a tube after condensation would otherwise stratify in a thick layer in a few seconds. With rapid steam velocities as shown in Fig. 8, all of the tube is hot because the air is continually carried away in the current of steam. Experiment has shown that this current is most active in producing heat transfer in front of the tube; the side about 90 per cent. active, and the back about 75 per cent. This indicates the importance of a staggered tube arrangement so that the front of each tube is presented to the steam flow.

The steam velocities must be sustained throughout the depth of the condenser, which not only requires proper tube spacing but a shell of decreasing width—that is, a wedge or heart-shaped shell terminating in a narrow, slot-shaped outlet. In this respect also the condenser is analogous to the turbine, Fig. 7, which has both changing blade height and changing wheel diameters.

If the foregoing conditions are maintained, the mixture of steam and air is kept homogeneous and the temperature does not fall until a surprisingly large percentage of steam has been abstracted and the process almost completed. Fig. 9 shows the relation between percentage of heat removed from an average steam-air mixture such as would enter a condenser, and the temperature of the mixture. Starting with approximately 92 deg. temperature there is no perceptible fall of temperature due to increasing air richness until over 99 per cent. of the heat has been abstracted and over 99 per cent. of the steam condensed. Thereafter the temperature falls with a marked knee in the curve, the exact position and shape of which depend on the proportion of air to steam in the original mixture.

This process is no longer rapid condensation but a matter of devaporization, to reduce vapor temperature and pressure and increase partial air pressure so that the air may be removed by a vacuum pump. It is best carried out in a chamber external to the main condenser forming a devaporizer or cooler. Figs. 10, 11, and 12 illustrate such an arrangement in which the flow of hot vapors and air taken from the bottom of the main condensing chamber is turned upward into a cooler from which the concentrated air is finally removed at the top. It will be noticed that this cooler is also of wedge shape, decreasing in area as the outlet is approached. The air is withdrawn by steam-jet augmenters which discharge into an intercondenser section forming part of the cooler. The air at reduced vacuum is then withdrawn and compressed to atmosphere by secondary steam jets or a small reciprocating pump. In one case a single small pump is used as a secondary for two condensers, steam-jet secondaries being installed as stand-bys.

The work of devaporization is done by cast-iron grids with fins, meshed together as illustrated in Fig. 13. Cold circulating water flows through the cores of the grids with only slight rise in temperature and then passes through

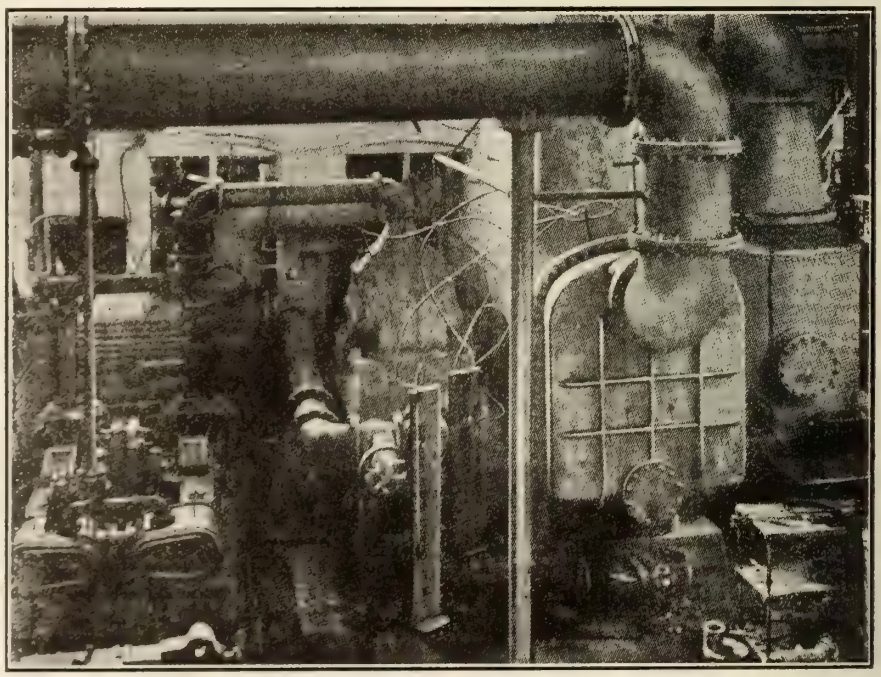

Fig. 11.—Large experimental surface condenser plant at works of Ingersoll Rand Co.

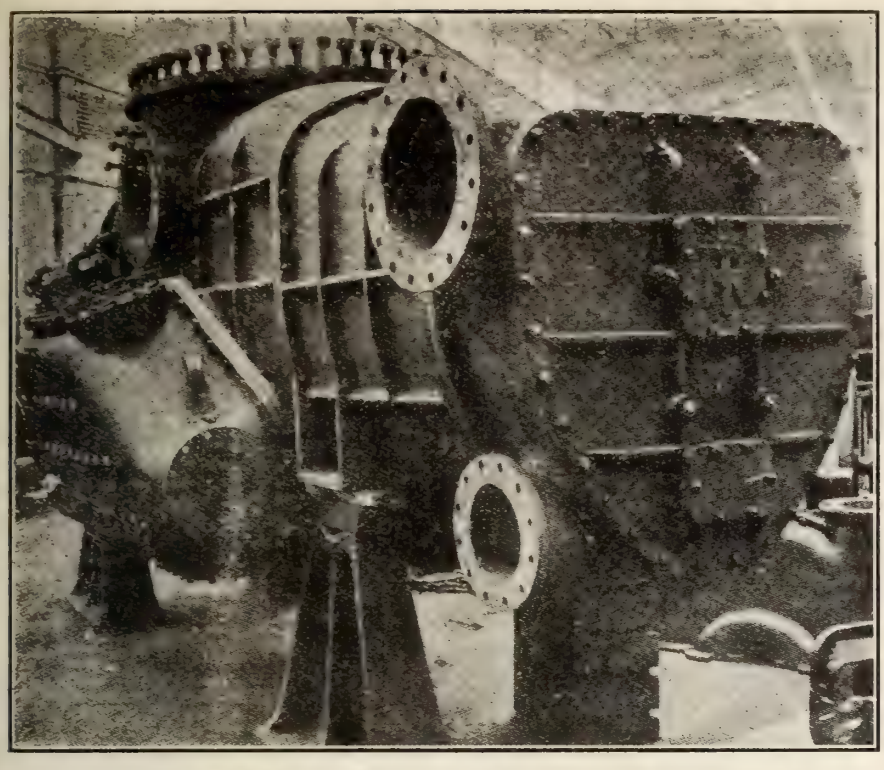

F'g. 12.—I-R Surface Condenser from inlet water box end. At the left is cooler mounted on shell.

the bottom group of tubes in the condenser (Fig. 10).

A large experimental plant, for capacities up to 70,000 lb. per hour was built at the Phillipsburg works of the Ingersoll-Rand Company to investigate these departures in design. The photograph reproduced in Fig. 11 illustrates the complete plant. By the use of electrical thermometers the performance of each row of tubes was determined and from that the efficiency of the tubes under all conditions of loads, vacuum and air leakage and in different parts of the condenser. A sliding or "trombone" thermometer of the electrical resistance type in the discharge water box was arranged so that it could be shifted to any position desired. Decks were fitted in the box which could be shifted to vary the water distribution so that a wide range of conditions of water circulation was obtained. It was found that high efficiency was obtained down to the last row of tubes of the condenser so long as certain critical conditions of vapor velocity were maintained. The condenser was hot throughout its depth and the condensate water at practically steam temperature. The hydrodynamic loss or pressure drop was also studied by the use of water manometers, from which spacings, and number rows were determined.

Fig. 13.—Showing Guds As Meshed When Assembled in cooler.

Depending on the air leakage, the cooler devaporizes and cools the air down as close to the temperature of the cold circulating water as one degree, thus giving complete countercurrent action. A study of these temperatures was made by electrical thermometers located at successive points as shown. As is well known from Dalton's law, the amount of air contained in a homogeneous flowing mixture of steam and air depends on the temperature and corresponding action gives maximum withdrawal capacity of the vacuum pump and protection against excessive reduction of vacuum due to heavy air leakage.

It is evident that with the cooler taking care of the process at the knee of the curve and the main condenser hot and active throughout its depth, water cannot pass through great groups of tubes without heating, and therefore the entire bulk of the circulating water can be heated with only one passage through the tubes instead of multiple passes. The circulating water may be pumped, therefore, at low head and power consumption, with high average rate of condensation since none of the tubes are wasted, or else at greatly increased velocities and correspondingly increased rates of condensation. The main supply of water passes directly through the upper and larger group of tubes and the remainder of water after passing through the cooler, goes through the lower and smaller group of tubes below the deck or partition.

The rate of condensation in a condenser with all its tubes active was found to vary substantially as the rate of condensation on a single tube, which, as is well known, depends on its diameter and material and the water velocity. With only one passage necessary, an entirely new basis for selection of velocity and tube size is opened to the designer. High velocity or small tubes or both can be used without excessive pump power as would be encountered with multiple-pass construction. Paradoxically, there is more insurance against corrosion, as well as greater protection against reduction of vacuum by scaling and sliming, when working the condensation rates. The author does not wish to imply that excessive pump powers should be used. High capacities and velocities may be obtained without exceeding circulating-pump powers now often used. The circulating-pump capacity is best arranged in twin units so that maximum water quantity and velocity are available in summer and can be reduced in winter by shutting down one pump. Variable or graded circulating-pump capacity is desirable in small as well as large units.

On large units having two water pumps, one of which is shut down in winter, provision can be made for preserving high velocities even with reduced water quantity. At high vacuum with cold water, the top tubes in large condensers do most of the work and therefore the smaller winter quantity should be concentrated on these tubes, thus maintaining high velocities in the tubes which tend to foul and corrode.

In the summer time both pumps supply water to the two nozzles (Fig. 14) serving sections A and B, and a small quantity of water is supplied the coolers and from them to section C at the bot-

Continued on page 27

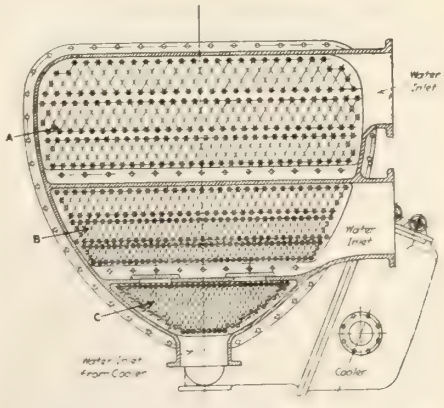

Fig. 14.—Water Box with two injection nozzles on I-R Surface Condenser.

Both nozzles are used in summer, the upper one only in winter, thus obtaining high water velocity even with reduced water quantities, and concentrating condensing action in top of condenser.

Report of the Bureau of Locomotive Inspection

A Summary of the Chief Inspector's Report for the Year Ending June 30, 1921. Some Points of Interest to the Stationary Engineer Are Embodied in This

INSPECTION in the U. S. is doing a great work, and its reports are always of considerable interest. The latest one to hand is no exception to this rule. The report under review is for the year ending June 30th, 1921.

The law covering the inspection of locomotive boilers in the U. S. came into force in the year 1912. Previous to that there were no statistics of accidents to boilers and fittings with which to make a comparison, but there is ample opportunity to make them between the year 1912 and the years in between up to the date of the present report.

The following tables show some of these comparative figures:

	1921	1920	1919	1918	1917
Number of locomotives inspected	60,812	49,471	59,772	41,611	47,542
Number found defective	30,207	25,529	34,557	22,196	25,909
Percentage found defective	50	52	58	53	54.5
Number ordered out of service	3,914	3,774	4,443	2,125	3,294
Total defects found	104,848	95,066	135,300	78,277	84,883

Number of accidents, number killed, and number injured as a result of failure of parts and appurtenances of the entire locomotive and tender, by years.

	1921	1920	1919	1918	1917
Number of accidents	735	843	565	641	616
Decrease from previous year (per cent)	12.8	[1]49.2	11.8	[1]4.1	.....
Number killed	64	66	57	46	62
Decrease from previous year (per cent)	3	[1]15.8	[1]23.9	25.8	.....
Number injured	800	916	647	756	721
Decrease from previous year (per cent)	12.6	[1]41.6	14.4	[1]4.8	....

[1] Increase.

The comparative table below for the fiscal years ended June 30, 1912, 1915, 1920, and 1921, shows the number of accidents, number of killed, and number of injured as a result of the failure of some part of appurtenance of the boiler only:

	1921	1920	1915	1912
Number of accidents	342	439	424	856
Number killed	51	48	13	91
Number injured	379	503	467	1,005

Derailments due to defects in or failure of some part of the locomotive or tender and the number of persons killed and injured as a result of such derailments for the fiscal years ended June 30, 1917-1921, inclusive.

	1921	1920	1919	1918	1917
Number of derailments[1]	8	7	7	2	4
Number killed	....	7	6	.....	1
Number injured	30	18	7	2	21

[1] Only derailments reported by carriers as being caused by defect in or failure of parts of the locomotive or tender were investigated or counted in this tabulation.

A comparison of the year 1915, in which the boiler law was amended, and the year 1921, shows the beneficial effect of proper inspection on the casualty lists.

Comparing the number of accidents, due to the failure of some part or appurtenance of the boiler, in the year 1912 with those in the year 1921 there is a reduction of 60 per cent. while in the number killed there is a 44 per cent. reduction, and 2 per cent in the number injured. It is noted in the report that explosions of boiler barrels, has practically ceased, and the failure of crown sheets has decreased considerably. It is noted however, that these failures are of a much more serious nature than formerly, as the number of killed is higher while the number of accidents is lower.

It is interesting to note that the report attributes the severity of these fire box failures to the use of autogenous welding. It states that where a failure takes place on a seam which has been welded, it is usually much more serious than it otherwise would have been. The report states that while autogenous welding can be safely applied on parts of the stayed surfaces of boilers, they should be avoided in fire boxes seams where overheating is likely to occur, such as crown sheet seams. It is shown that where these welded seams are involved in accidents, 80 per cent of them fail, and that therefore welded seams should not be used unless the stresses on the part are carried by other construction apart from the welding.

This does not mean to say that autogenous welding must not be used in any case, but that where the stresses coming on the plate are only resisted by a welded seam, it is not sufficient to give the requisite margin of safety. The report says "This at least until some means has been developed through which the quality and tenacity of the weld may be established in advance of its failure."

The report then gives some figures on the energy contained in water under pressure, and on the energy liberated in a particular case. The actual words of this portion are "The force of a boiler explosion is in proportion to the size and suddenness of the initial rupture, and the temperature and volume of the water in the boiler. The average modern boiler has a capacity of approximately 500 cubic feet of water below the crown sheet and has a steam space of about 150 cubic feet. If such a boiler with 200 pounds pressure ruptures from any cause, so as to suddenly reduce the pressure to that of atmosphere, the released energy will amount to approximately 700,000,000 foot pounds and if the explosion took place in two seconds approximately 90,000 horse power would be developed." The causes of boiler explosions are given as abnormal steam pressure, weakness in design or construction, improper workmanship, corrosion or wasting away of material, broken or defective stays, overheated crown or fire box sheets.

Water Gauge Glasses

The report draws attention to the difficulty of securing a correct indication of the height of water over the crown sheet under all conditions of service. It has been established by the Bureau's investigations that gauge cocks screwed directly into the shell of the boiler do not give correct indications while steam is rapidly escaping from the boiler, and the use of a water column with try cocks and a glass gauge is recommended.

Fire Doors

The report strongly recommends that all boilers on which oil fuel is not being used should have a mechanically operated fire door, which can be operated by a foot pedal situated at a proper distance from the door, so that it can be closed without the fireman or engineer having to stand in front of the fire while so doing. This recommendation is the result of so many accidents happening through failure of tubes or sheets by which the steam pressure has been liberated into the fire, blowing it out along with steam and boiling water into the cab of the locomotive. As these accidents often happen while coal is being put in the furnace, the mechanically operated door is regarded as a safe guard. It also tends to longer life of the boiler and better economy, as the door would be shut between each shovelful of coal, and the tendency to cause cracks round the door through cold air striking the plates would be minimised.

This automatic door is not a new thing, having been used in connection with water tube boilers in both the British and U. S. navies, and being compulsory in several states of the Union.

Injectors

An instance is given where the bonnet of the steam inlet of an injector blew off, resulting in the death of an employee. The cause of this was a thread on the bonnet that had been worn to such an extent that the bonnet dropped in up to the two last threads before the threads engaged. The damage to the

threads had been caused by the use of hammer and chisel for slacking off and tightening the bonnet, and such practice is strongly deprecated.

This is a point that could be well borne in mind by a good many engineers, who are very apt to use this method in preference to taking the trouble to find the proper spanner or wrench to do the job.

The general trend of the report would show that since the inspection law has been in force a considerable decrease in accidents has taken place, and emphasises the beneficial effect of such inspections when properly carried out.

There can be little doubt of this, as it has been the experience of every place where a thoroughly enforced inspection law has been put into force, and where the inspectors employed have been up to the requisite standard.

EDUCATION AND FUEL CONSERVATION

The average steam plant wastes one quarter of its fuel. The domestic consumer of fuel is even more wasteful than the industrial consumer. The mineral fuels can never be replaced. Once exhausted they will be gone forever, and there is not—as is popularly supposed—an inexhaustible supply. Oil is going fast; anthracite will soon be gone; and the thick-vein low volatile coals of the eastern field are almost gone. The problem of fuel conservation is therefore, one of world importance to all of the people of all the world.

The many problems that have a bearing upon fuel economy are of vital importance to the individual fuel consumer. He pays for the fuel that he uses and his annual bill depends upon two things, viz: the price per ton or per gallon that he must pay and the quantity that he uses. He has no control—or at the best, the most remote control—over prices, but he does have a large measure of control of the quantity that he uses. The average consumer can reduce the quantity of the fuel that he uses at least twenty-five per cent. This is the estimate of many competent engineering authorities.

Let us, for example, suppose an industrial concern needlessly wasting one-quarter of its fuel. Every dollar that is saved to the fuel account can be passed to the dividend account. Every stockholder of every company relying upon steam power should be deeply concerned with the fuel bill, because fuel is a very large item of manufacturing expense in nearly all industries. We are entering upon days of very sharp competition and the industries to survive will be those that give close attention to the cost of production.

Fuel economy depends primarily upon the education of all those who have anything to do with the final uses of fuel—from the manager in his office, down to the men who actually burn the coal, oil or gas. Knowledge is necessary, no matter how refined the equipment for the utilization of the fuel may be. The more refined the equipment, the more refined the knowledge must be.

The United States Fuel Administration very early in its short-lived career, realized that education was the real key to fuel economy and it set about a campaign of instruction. The work of the Fuel Administration came to an end with the close of the Great War, but in giving up its campaign it reported as probably its most important finding and message to the country, that the work of conservation must go on primarily through the better education of the American citizen in the theory and practice of combustion. The man who studies fuel economy is certain to effect fuel economy.

BOOK REVIEW.

We have received from the U. P. C. Book Company, 249 West 39th Street, New York, "Burning Liquid Fuel," by William Newton Best, F. R. S. A., A. S. M. E., etc. The book contains a foreword by Rear Admiral John R. Edwards, U. S. N., in which he calls attention to the peculiar fitness of the author to deal with this subject. There is also a preface by the author.

The first chapter is devoted to the author's early experience in the use of oil fuel, which goes back to the time of his superintendency of the Los Angeles Electric Railway in 1887. Since those days Mr. Best has equipped practically every form of furnace in existence with oil fuel burning apparatus, and therefore is well qualified to speak on the results attained and to be acquainted with different installations. The origin production and analysis of liquid fuel are dealt with in chapter two, and this chapter contains a fund of information on these departments of the subject. Atomisation, oil systems, locomotive equipment and marine and stationary boiler equipments are dealt with in subsequent chapters. Refractory materials for use with oil furnaces, commercial gas practice, heat treatment furnaces, forge shop, sugar industry, etc., are dealt with very fully.

A feature of the book is the profusion and excellence of the illustrations. The volume fills a very long felt want, and is the most complete treatise on this subject that has come to our knowledge. The book sells for $5 net in the United States.

OTTAWA LODGE C. A. S. E.

Ottawa Lodge, No. 6, C. A. S. E. held one of its special open Educational Meetings on Wednesday evening, February 22nd, in their (Huckels) Hall, Cor. Bank & Frank Streets.

The subject of the evening was a very interesting lecture on Refrigeration, which was very ably given by Bro. Arthur G. Pedder, A. M. E. I. C., of the Ottawa Electric Company, accompanied by lantern slides.

There was a very large attendance of members and visitors and to judge by the interest taken by all present, Bro. Pedder's lecture was a huge success and highly appreciated by all.

Ottawa Lodge is coming forward steadily and adding some excellent and valuable material to her already good list of workers.

TORONTO LODGE C. A. S. E.

At a recent meeting of the C. A. S. E. Toronto, No. 1, Mr. Jno. Farmer, M. E. of No. 314 Caristine Bldg., Montreal, gave a very interesting lecture on the means for determining CO_2 and the importance of CO, recorders. Because of the very general lack of information on the above subject his lecture was more or less elementary and yet it proved very interesting. There was a very good attendance and a very hearty vote of thanks was extended Mr. Farmer.

Anyone who attended the lecture will hereafter say they have "No Cash."

GUARD THE OIL CAN

It is doubtful if any single piece of shop equipment gets less consideration than the small oil can which is so often seen resting on or near every class of machine tool. Yet the efficiency of the mechanism depends in no small measure on the careful and judicious handling of this small can. The purpose of the oil can is to store small quantities of lubricating oil so that the same can be conveniently applied when occasion requires.

When oiling bearings or sliding surfaces it is important to guard against any foreign substance getting into the oil holes or passages that will destroy or interfere with the free movement of the parts; and yet how often will an observer see an oil can knocked off a machine into a pile of cuttings or dirt, and picked up and used without any attempt to clean the spout before inserting it in an oil cup or oil hole. This form of neglect or carelessness may not be a general one but it is common enough to bring to the attention of those readers who may be desirous of seeing the "insignificant oil can" given the attention it is duly entitled to.

A NEW TYPE OF HIGH EFFICIENCY CONDENSER

Continued from page 25

tom of the condenser. In winter one pump is shut down, the valve to section B shut, and the plates in the deck between B and C removed thus throwing these two tube banks in parallel so that they both receive water from the coolers. The main water supply is then concentrated on the upper section A. This design also has the advantage that at any time the entire capacity of the two pumps may be concentrated on section A or B, thereby producing extremely high cleaning velocities, also, that either section A or B can be shut down independently and the water-box covers removed for inspection or cleaning.

Compounding the Combustion Engine

After Years of Research a Compound Type of Internal Combustion Engine Has Been Developed and Has Been Subjected to Long and Continuous Runs—The Engine is Four Cycle

By Elmer A. Sperry
President The Sperry Gyroscope Company, M.A.S.M.E. Paper Read Before The American Society of Mechanical Engineers.

THE high-compression or Diesel cycle in combustion engines has worked nothing short of a revolution, having brought to the prime mover its choicest heritage, the highest thermodynamic efficiency known. The fuel economies of these engines have forced them to the front. They have become extremely reliable and easy to operate; instances are becoming common of long runs without overhaul—long-continued performance without shutdown or forced stop of any kind.

As experience is gained with these engines however, there have developed some objectionable features which are serious. Though they occupy somewhat less space than boilers and engines, the weights of Diesels are on a par with, if not somewhat in excess of, those of reciprocating engines with their boilers and decidedly in excess of those of water-tube boilers and turbines. The standard product of the largest builder of Diesel engines for the merchant service weighs about 450 lb. per shaft horsepower and is large and bulky. A substantial increase in tonnage of freight carried is only one of the gains that would be secured, could these engines be made much lighter and smaller for the same power.

The weight is not the only difficulty with these large engines, however, for they cost more than steam equipment of equal power. One instance of $200,000 excess for a 3,500-s. h. p. ship is cited. In another ship for the same service and of the same power the weight was 60 per cent. in excess of the turbine equipment and the cost 212 per cent. amounting to $306,000 excess. Notwithstanding this extra capital charge, the first ship at three-fourths capacity in the Far East trade can earn nearly double net (83 per cent.) over its turbine competitor of the same power and construction and with its machinery weighing a third more than steam equipment.

Again, it has been found that almost without exception a grade of fuel oil known as Diesel oil must be employed. This is a partially refined product costing upon the present market considerably more than bunker oil burned under the boilers.

The fuel-oil problem in itself renders some advance absolutely imperative. Conservation of our oil should be backed by Government enforcement to stop the prodigal waste which results from bulk or furnace firing of enormous quantities of these highly concentrated fuels, destroying three to five times the quantity, power for power, required by steam, especially now since the cheapest petroleum can yield to the full its wonderful store of energy in the most direct way possible by being burned drop by drop directly in the cylinder and practically at the point where the work is to be done.

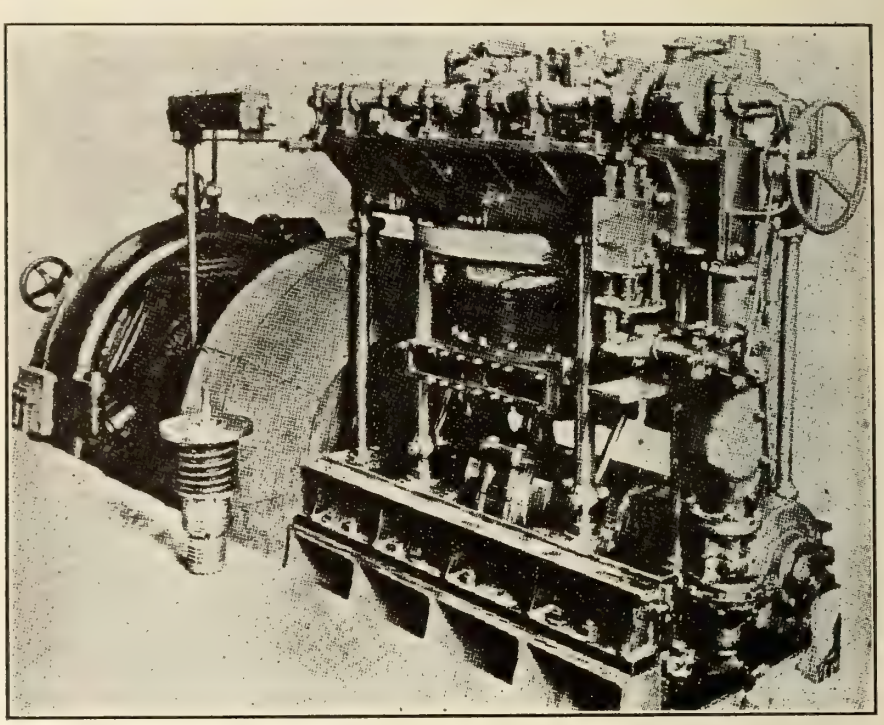

Fig. 1.—10 to 1 compound oil engine built for heavy duty.

Compounding as a Remedy For Inherent Difficulties With Diesels—The Author's Early Work.

In a report made by a group of engineers in 1900, it was stated that if the combustion engine could be successfully compounded, a most important gain would be made in its weight and size. The fact that compounding presents other advantages has been known to engineers for a number of years, but the difficulties have been looked upon as insurmountable.

A year ago Professor Watkinson, director of the important engineering laboratories of Liverpool University, in discussing an epoch-making paper by Engineer-Commander Hawkes on the Admiralty's extensive research on Diesels, stated, in substance, that we must recognize that the combustion engine in its present state was very crude and in compounding only lies the line along which the next great step in progress would be made. And he also stated that much greater results are bound to follow the compounding of combustion engines than were ever realized by compounding steam engines; first, because of the very much greater range of pressures available, and secondly, because the great enemy to compounding in steam, viz., condensation, is not present.

Activity in this field is now prodigious and workers in various parts of the world are commencing to realize that a great advance step is imminent. In America, a group headed by the author has been engaged on this problem for upward of thirty years. Starting in 1890, his first compound was running before the World's Fair. The patent records give evidence of this early work under date of December 10, 1892. A number of engines have steadily followed each other, each involving improvements resulting from previous experience, until the essential problems have been conquered. Not only has the principle been thoroughly established, but all the important refinements have been subjected to long continuous runs. Data almost invaluable to the art have been secured, together with a series of indicator cards and diagrams that exceed a thousand in number.

The outcome has been that the various prophecies of thoughtful engineers in the past have been more than fulfilled and there is every evidence that the heavy-duty compound combustion engine is everything that was hoped for. It is light compared with the normal

Diesel, being in special cases less than one-tenth, and in some instances less than one-twentieth, in weight for the same output. Its mechanical efficiency is extremely high and a distinct gain in overall efficiency from fuel to shaft has been made, as well as a very definite gain in simplicity, direct performance and smoothness of the crankshaft diagram. This has been achieved while adhering to the best practice, namely, four-cycle operation.

Compounds Lighter and Cheaper—Much Larger Units Possible

The lightness and simplicity of the compound solves the capital-charge factor automatically. Engines of this type weighing only a fraction of the weight of the present Diesel will inevitably be found to be much less in first cost as well as in cost of upkeep.

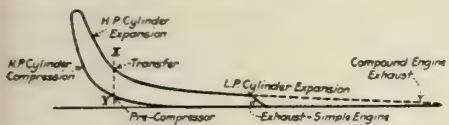

Fig. 2.—Indicator card of compound Diesel Engine.

Much higher powers than are now available are thought to be of extreme importance and much interest is centered upon the question; in fact, the more advanced among the Diesel builders are to-day concentrating upon ways and means to attain still higher powers from a single cylinder working on its present cycle. Of course this will increase instead of decrease the weight per horsepower. It is to the compound that we must look for a solution of this problem, for the reason that within present cylinder and cylinder-wall limitations, powers in excess of 10,000 h.p. per engine are entirely practicable and are accompanied by all the proportionate savings in weight, space and capital charge that have been pointed out.

Our own Government has watched the progress of this work for a number of years, inspected the development in its various stages, and has come forward with orders for an initial engine which, together with orders from other sources, is now under construction. To illustrate to what low figures the compound principle can be relied upon to bring the heavy-oil engine, it should be stated that among these orders is one now under construction to weigh about five pounds to the brake horsepower. This may be looked upon as extreme, but the designed weights and finished parts as they now stand are below this figure. This brings us within striking distance of aviation engines, where the fire risk through the presence of gasoline and the electric ignition system constitutes one of the greatest menaces to aviation progress. The remarkably high mean effective pressures of the heavy-oil compound will give us the aviation engine and entirely eliminate both these sources of fire risk.

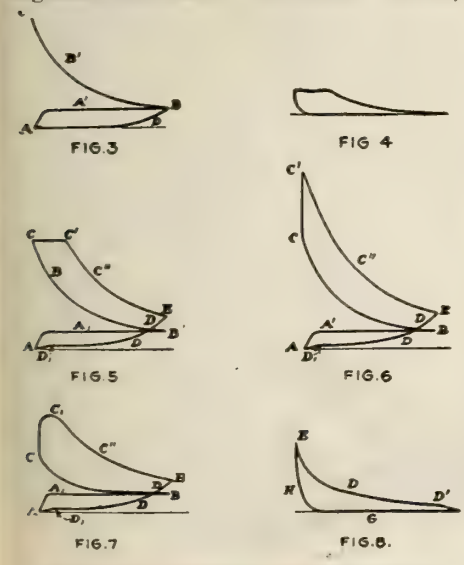

Fig. 3 to 8:—Indicator cards of compound cycle.

The reason for the great weight in all classes of Diesel engines is apparent when it is understood that they are designed around an extremely small quantity of air and oxygen at each stroke, an amount so minute as to be quite surprising when compared to the ponderous engine itself. The volume of the power gases available to do the work is limited to the size of the combustion space, and when it is remembered that this is confined to a small crevice in the end of the cylinder of the order of one-twentieth of the travel of the piston, the limitation is at once seen. Attempts to make it larger produce both compression and ignition temperatures that are too low and we have semi-Diesel and surface-ignition engines confined to smaller sizes with tendencies to a lower grade of performance. Such engines are difficult to start and represent no gain in weight.

Two of these volumes are sometimes combined as in the opposed-piston Junkers engine. The size of the combustion space, though still minute, is known to give some small advantages over the regular engine which has only one-half of this space, but has the disadvantage in common with all two-cycle engines of the fractional piston-ring support practically without lubrication on the hot bridges as the exhaust port is uncovered by the piston.

Separate Cylinders Suited to Pressure Ranges—Two Stage Compression Secures Large Working Volumes

Take, for instance, the Diesel indicator card, Fig 2. Draw the vertical line XY and it is easy to see that the expansion pressures to the left are high and should do their work in a high-pressure cylinder, whereas those to the right, especially following the dotted extension line of expansion, are definitely low pressures and should do their work in a low pressure cylinder for the purpose. This is practically all that is attempted in compounding combustion engines. The vertical line XY also divides the compression curve into two stages, low and high, the latter taking place in the combustion cylinder proper as a second stage. No compressor delivering 500 or more pounds per square inch will undertake to do so in a single stage; there would be at least two stages. The old single-stage compression is discarded in the compound and this modern method of two-stage compression is adopted.

Supercharging or compressing in two stages gives the controlling advantage in that a very much larger unit volume of gases may be handled. The clearance spaces may be many times the size of those in the Diesel, and yet it is perfectly simple to bring these large volumes up to the requisite pressure and incandescent temperatures at the instant of fuel injection.

The large volume of power gases in the combustion chamber of the compound at once solves a number of important problems, makes the light engine easy of accomplishment, and overcomes a number of other difficulties at the same time. No longer is the chilled perimeter per unit volume of gas the controlling factor, as it is in the Diesel. The chilled walls are retired into the background as the large volume asserts itself, as compared with the small crevice indicating the total volume available in the normal Diesel (shown at C in Fig. 9), where the chilled areas exposed are very large and the volume very small. At a glance it will be seen that all this is reversed completely in the large dome-shaped clearance space D in Fig. 9, where the volume has increased very much more rapidly than the perimeter. This is again vastly increased in the low-pressure cylinder, where an extremely large volume exists with still smaller ratio of chilled perimeter. Taking all of the chambers into consideration, it is found that while retaining all of the chilled walls that are necessary for proper handling of the lubrication, still a gain is made on the order of 60 per cent. in the extent of these chilled walls in the compound as compared with the simple engine.

With the large clearance volume we no longer have difficulty with solid injection, nor do we have any difficulty in using a wide range of heavy fuels. It has been known for years that as soon as the oil spray encounters chilled or even red-hot walls, the efficiency drops. Here the oil fog may penetrate the deep masses of hot compressed air with instantaneous effect in every direction from the spray nozzle without encountering chilled walls and instantaneous and very complete combustion results. In the compound engine the clearance volume is so large that the entire high-pressure piston displacement causes it to lose only a fraction of its pressure, thus bringing to the second stage, or low-pressure, both ample volume and pressure so that this piston (representing 6, 8 or even 10 times the area of the high-pressure) is driven to the end of its stroke with pressures still above the atmosphere.

Much Greater Expansion, Higher Efficiences

In this way the engine yields an expansion ratio based on gage pressures,

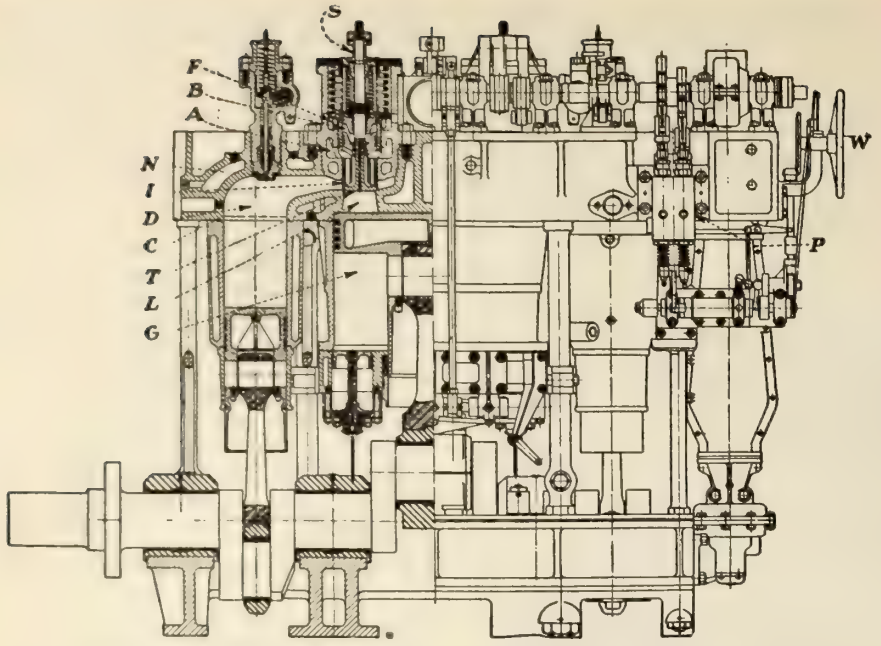

Fig. 9.—Section and elevation of compound oil engine showing construction.

which instead of being 3 or 4 to 1, as in the case of the automobile engine, or made as high as 120 to 1, yielding a higher return and greater efficiency from the fuel because of the lower temperature of the exhaust. The great volume in the combustion space furthermore allows this space, without distortion, to extend easily out over the top of the low-pressure piston, making a most direct connection therewith through short transfer port (see L, Fig. 9).

Fig. 3 shows the cycle card without fuel, taken from the high-pressure cylinder in a 10: 1 compound. The first-stage compression enters the cylinder at point A on its out stroke with the pressure about 113 lb., giving a power stroke indicated by line A. At point B the induction valve closes and on the in stroke the compression proper starts and rises on line B' to Diesel values at C. There being no fuel injection, the receding stroke brings the pressure down on practically the same line B' to point B (E in Figs. 5 and 6). Here the transfer valve opens and the gases pass on the in stroke to the low-pressure cylinder on line D. This is the out stroke of the low-pressure, the pressures sinking to a trifle below atmosphere before the final exhaust valve opens and continues open nearly during the entire next stroke of the low-pressure piston, which is, however, never shown on this high-pressure card but on the low-pressure card, Fig. 4.

Fig. 4 is the air-pump card representing the first stage of the compressor which delivers air to a small receiver, from which air is delivered during the induction stroke, on line A' of Fig. 3, which, it will be observed, is a power stroke with a high mean effective pressure, thus recovering some of the power of the pump.

Fig. 5 is the same as Fig. 3, except that fuel has been injected, and shows the regular slow Diesel burning common to all early cards of these compound engines, where from point C a perfectly level line is often drawn to point C" which marks the point of "cut-off." The gases then expand on line C" to point E, where the transfer valve opens and the gases continue to do work on a large area of the low-pressure piston, indicated by line D. The exhaust valve opens with pressures only slightly above atmosphere at point D'. The ordinary slow Diesel burning has the objection of lower efficiencies and allowing the heat to be added to the gases out nearer the exhaust end of the stroke.

Utilizing the Detonation of Fuels

Through a research extending over a year and a half or more, conditions were discovered by means of which "detonation" of the fuels may invariably be secured. This extends to a large variety, including of course the heavy fuels. While automotive engineers have adopted extreme measures, even lowering compression, "doping" fuels, etc., etc., in order to avoid the detonation, we have been working in the opposite direction. We have found that the thermodynamic efficiency is higher in case of high detonation diagrams than with low. Our work has been toward realizing these high efficiencies by developing instead of suppressing this high-intensity combustion. We have therefore sought to harness and utilize to the full the detonation phenomenon for the reasons and with the results outlined herein.

Fig. 6 is a typical card taken under the same conditions and the same engine as Figs. 3 and 5, exhibiting "detonation" and showing the quick burning, piling the heat up at the beginning of the stroke and as far away as possible from the exhaust end, giving also a very much truer Carnot-cycle card. All recent running of the compound engines has been in accordance with this card. One of the achievements of high-intensity combustion is better thermal efficiency and a still further reduction in the exhaust temperatures. The engine with this type of card is lifted from the old constant-pressure to the superior con-

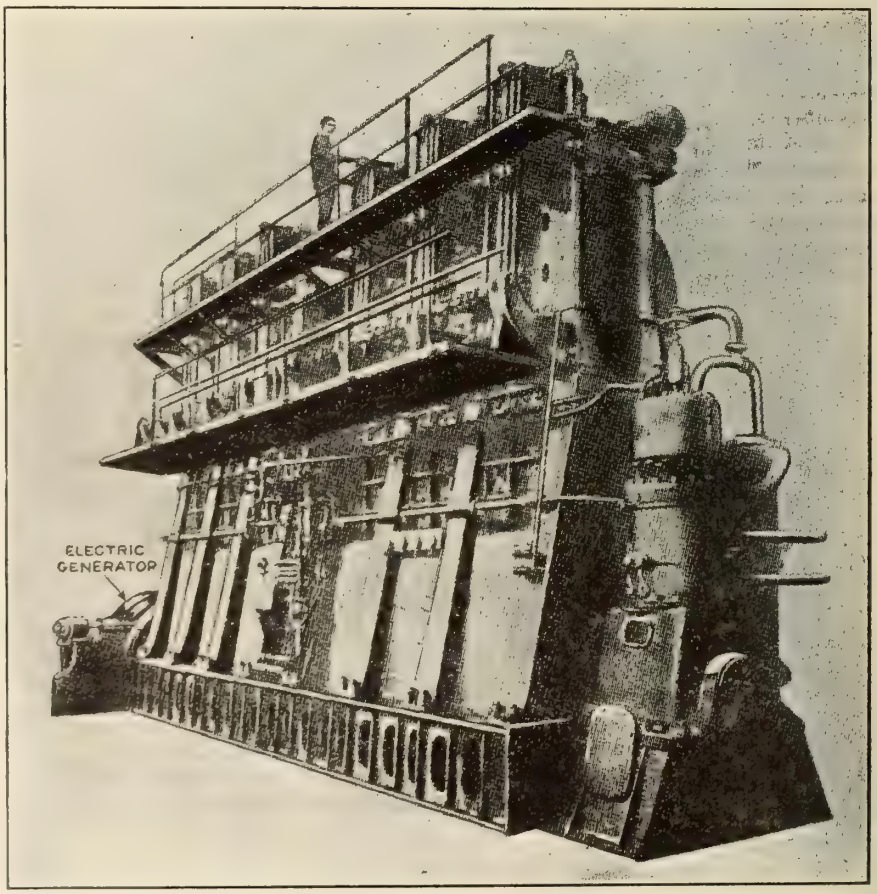

Fig. 10.—Standard type marine Diesel.

stant-volume performance which frees the compound from all speed limitations. The detonation characteristics, e.g., the vertical rise on the diagram, persist even at very high speeds. This card also insures operation at lower fractional powers without indication of carbon deposits.

Fig. 7 is given as showing the range of control of the peak and shape of the card at will under the same operating conditions and with the same spray nozzle.

Elimination of Losses in Transfer

In early attempts at compounding, principally layouts, it was found that prohibtive losses would occur in the transfer, due to the falling pressures while filling the low-pressure clearances. A complete solution of this is found in a special adaptation of the process of "cushioning"—closing the exhaust valve at a predetermined point before the outgases and cushioning them up to the transfer pressure so the transfer valve opens under conditions of equal pressure on each side. There are practically no losses sustained in cushioning; the power of compression is returned very completely on expansion. The additional advantage is secured of preventing all erosion due to high velocities of the hot gases over the transfer seats. These seats are amply jacketed and are found to remain smooth, bright and perfectly sealed over long periods. It is incidentally found that in cushioning, the adiabatic compression of the hot gases brings with it an equality of temperatures as well as pressures, so there is neither loss in pressure nor temperature at this critical point of transfer and the efficiencies are carried at high values throughout the cycle.

Fig. 8 shows the low-pressure card, indicating the same power pressure line D as Figs. 3, 5 and 6. On this in stroke the exhaust valve opens at D′ and closes again at point G on the out stroke, giving rise to the cushioning curve H, terminating at the same pressure and really the same temperature as at E in the high-pressure cylinder.

The Transfer-Valve Problem

The point X in Fig. 2 will be recognized as being the same as point B in Fig. 3 and point E in Figs. 5 and 6. The transfer valve considered as an exhaust valve is here called upon to handle much hotter gases than ever heretofore. It must be remembered, however, that compression in the compound is by the modern two-stage method. Air is admitted to the combustion chamber under comparatively high pressure and although it is warm, yet with each atmosphere of pressure its cooling powers are doubled. Air at 100 lb. thus has seven times the cooling power of atmospheric air, seven times the weight and seven times the molecules in contact for cooling. In forcing the high-pressure piston down on pressure line A′ in the above figures, air must pass some port in entering. Now, as a matter of fact, this port is in line with the transfer port and the induction valve itself rides on the back of the transfer valve in the form of a hollow sleeve I (Fig. 9) seated directly on the top of the transfer valve T. The back of the transfer valve is provided with greatly enlarged radiating and cooling surfaces presented to this cooling air and powerful convection currents are constantly acting when sealed. Moreover, this air when entering is at high velocity and gushes down through and bathes the deeply serrated surfaces of the back of the transfer valve, licking up the heat very completely in its inward rush.

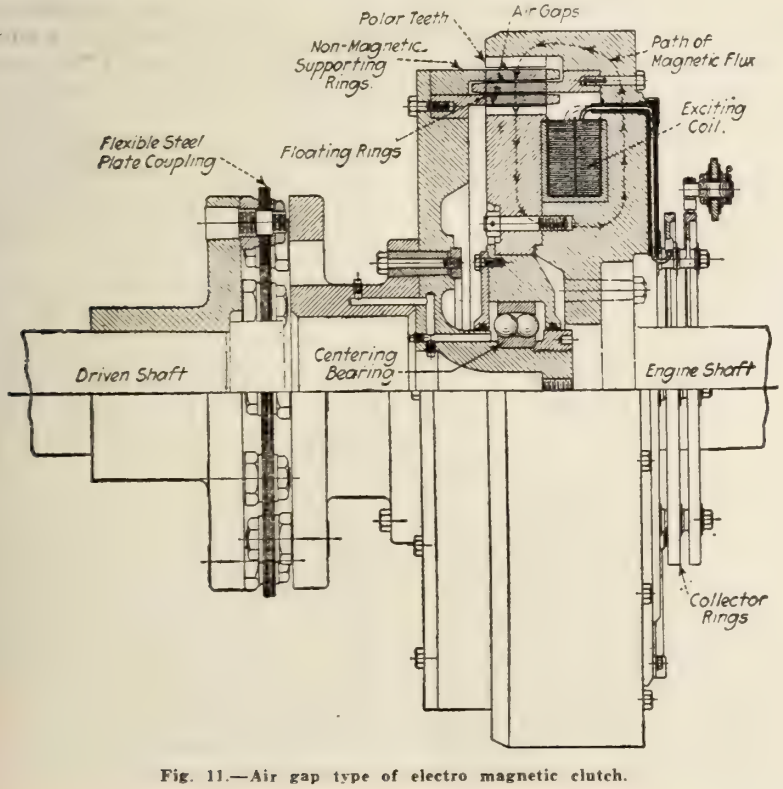

Fig. 11.—Air gap type of electro magnetic clutch.

Now in following out the cycle, it will be noticed that this is the very step that follows directly on the heels of the transfer of the hot gases (D, Fig. 3) and continues throughout the next quarter cycle (see A′ Fig. 3) and through the entire descent of the high-pressure piston, which in this way delivers a real power stroke to the crank with mean effectives in some instances greater than the mean effective pressures of the ordinary Diesel, thus returning some of the power taken to drive the supercharger or first-stage pump. If the transfer valve is intensely heated on its under surface (see T, Fig. 9) and is then instantly intensely cooled on a surface five times as great, it will certainly strike and maintain a heat balance which in practice is found to be extremely low. only about one-half the temperature of the Liberty valves, nowhere nearly approaching red heat nor the temperature of normal Diesel exhaust valves under load conditions.

Again, the heat in these gases absorbed from the hot valve is useful inasmuch as it is the auto-ignition temperatures as well as pressures that are required at the end of the compression curve B′ Here a useful heat transfer and pure regenerative process is carried out. The seats give no trouble because they are backed by the ample water jackets and, in fact, the whole transfer valve gear operates continuously and successfully and is found to be in perfect condition after hundreds and even thousands of hours of operation.

How Lightness is Obtained in the Compound Engine

The question often asked is, to just what is due the smallness and lightness of the compound engine? It is this: In the four-cycle Diesel we have the tonnage of metal due to the presence of high pressures operating at a ridiculously low material efficiency because these high pressures persist only about 2½ per cent. of the total time. The Diesel card rises abruptly and immediately falls. All the rest of the time, over 95 per cent., either low pressures or no pressures at all are present, whereas in the compound the pressures persist and we are dealing with great blocks of power, as can be seen from the power curve C″. Although the pressures are not materially higher than in Diesel practice, they are made to persist practically clear across the card, producing a very large gross mean effective. This is instantly followed by another line clear across the card, again producing another large gross mean effective in the low-pressure cylinder when referred to the high-pressure area, all from a single fuel injection. Instead of 60 to 70 lb. net mean effective to the crank, delivering its power through a few degrees only of one stroke in four, in the compound we have two net mean effectives, each of 300 or 400 lb. sq. in., succeeding each other and covering two strokes out of the four from a single fuel injection, giving very much better crank-effort distribution for power purposes. The

point of paramount interest is that these two large blocks of power are secured not by any material increase of pressures, but by using large quantities of power gases, and "hanging on" to the pressures we have in those gases throughout practically two complete strokes, clear across the card twice, thus abstracting much more of the power they contain before exhausting. Suppose these to be 330 lb. per sq. in. each. Added they make 660, which is easily ten times 62 lb., a net mean effective not infrequently met with in ordinary Diesels. In an engine of simple construction giving ten times the net mean effective to its crankshaft and well distributed, there should be no good reason why it should weigh more than one-tenth the weight of the present Diesel.

The power gases work in the Diesel about 120 deg. of arc and in the compound 315 deg., or 2.6 times as long; or, considering the points of "cut-off" in each, the true expansion curve is 3-1/3 times as long, which accounts for its large mean effectives and higher economies.

Proper Ratio for Compounds

As to the proper ratio for compounds, engine of 10: 1 ratio of low-pressure to high-pressure cylinder areas, also 8: 1 and 6: 1 have been made, operated and studied, the smaller ratios being at present considered more desirable. The weight factor does not change materially with changes in ratio in this region. The low-pressure piston operates two-cycle. The power distribution and the weight of the reciprocating parts both equalize best at about 6: 1. This makes a perfectly balanced unit, the end masses equaling and also moving oppositely to the central. The two full power impulses following each fuel injection are also about equal. Thus full four-cylinder performances are secured with only three cranks and two extra power impulses are delivered on the induction stroke (see line A', Fig. 3), making six power impulses for each cycle.

Another unusual advance should be noted, viz., complete reversibility and self air starting are secured without additional valves or cams over the simple, one-way engine without air starting, there being no difference in this regard. Again comparing the full-reversing, air-starting compound unit with a similar four-cylinder Diesel of any prominent make, delivering the same number of primary power impulses to the crank, the latter has 16 valves and 32 cams. The former operates the same cycle with two extra power impulses over the Diesel with 5 cams driving 7 valves.

Doing away with the three-stage air injection pump, its intercoolers and general complexity is another important simplification. One United States builder stated recently that an excess of 11 per cent. of the entire power of the engine is absorbed for driving these pumps.

Marine Type of Compound Engine

Fig. 1 shows a 10 : 1 compound engine built for heavy duty. Although this is a small marine type with high-pressure cylinders 7 in. by 11 in. running at 400 r.p.m., yet the size of the crank-pitman end in the lower center of the engine reveals the ruggedness of these parts. The fuel pumps are also shown here and the connection to the governor. The camshaft is on a shelf at the top of the engine to one side and is driven by skew gears. The electric generator forming the full load of this engine is shown in the background and one of the transfer valves with its bonnet cover stands on comparatively small size of the engine, although in the foreground, is notable and stands out in marked contrast with the engine of Fig 10, the product of the largest Diesel builder. This is the standard marine engine for some seventy ships. The electric generator forming the full load of this engine (so marked) is also in the background, as in Fig. 1. The generators in the two cases of course being standard, give an unusually excellent basis of comparison. The compound works at a piston speed of about 700 feet per minute and its generator would be still smaller in comparison, should it be worked at the piston speed of about 900 feet per minute of the large engine. Incidentally, in the foreground of Fig. 10 there is also an excellent illustration of the three-stage, intercooled, high-compression air pump for spraying the fuel into the cylinders.

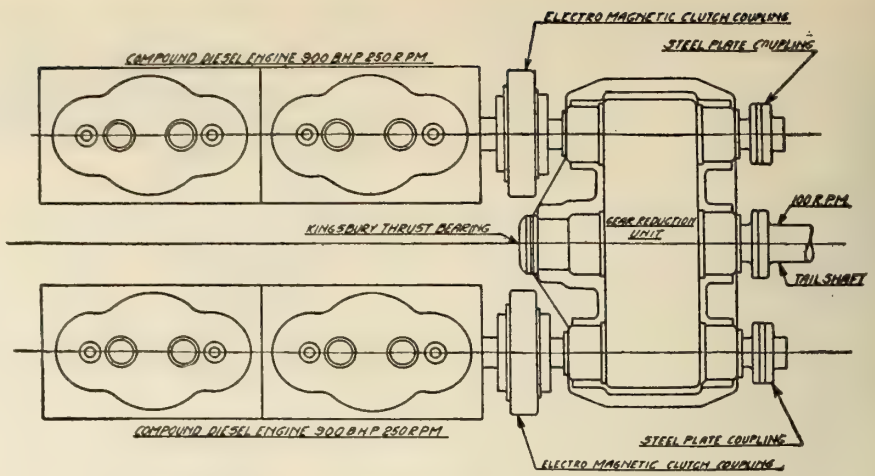

Fig. 12.—Plan of proposed installation of propelling machinery.

The large size and weight in the Diesels extends to all makes in somewhat different degrees. A line of Diesels made in the United States are reported to weigh 512 lb. per b.hp. The engine of Fig. 10 weighs 450 lb. per b.hp., while the compound in Fig. 1 weighs less than 30 lb. per b.hp.

Internal Construction of the Compound

Now as to the construction of the compound, Fig. 9 shows an elevation to the right of the center, and longitudinal section to the left, of the engine shown in Fig. 1. The two high-pressure or combustion pistons on their out stroke are at the ends and in the center the low-pressure at its extreme in stroke. The sturdy construction is indicated by the size of the crankshaft, about 50 per cent. larger than in any other combustion engine of which the author has knowledge, approaching, as it does, the bore of the combustion cylinders themselves. The fuel pumps P and the control and manipulating wheel W are shown in elevation to the right. To the left the large dome of clearance D, forming the combustion chamber of the compound, stands out in marked contrast to standard Diesel practice, which is shown by the little space C between the solid horizontal line at the base of the clearance and the dotted horizontal line just above. The dome is large and forms an upward extension of the combustion cylinder, extending also to the right in a large sweep surrounding the transfer valve T which seals the transfer port L. The sleeve-like induction valve I is shown seated on top of the transfer valve and is controlled by the cam-operated fork F. The transfer valve and sleeve are lifted by a fork not shown, located in thimble S near the top of the stem. The first-stage annular compression pump G surrounding the trunk piston below the low-pressure piston proper, delivers its air to a small receiver, which in turn discharges to the cored port A surrounding the induction sleeve I, the cooling action of which has been described. The little balancing cylinder B sustains a permanent connection with the low-pressure cylinder. The solid-fuel injection valve and nozzle N are placed approximately over the center of gravity of the large masses of air in the clearance dome D.

The comparison with the large dome constituting the clearance and combustion space in this compound with the small distance between the solid horizontal line at the base of the combustion space in Fig. 9 and the dotted line indicating the combustion space C in the normal Diesel, is simple to make and is significant.

It is understood that the two high-pressure cylinders are operating four-cycle, one 360 deg. back of the other, discharging alternately into the low-pressure, which therefore works two-cycle and delivers power on each down stroke. The cycle has been pointed out and the general operation will be apparent from this figure.

Field of Usefulness of the New Prime

To engineers versed in the problems of selecting and designing prime movers,

the advantages of the compound combustion engine are readily apparent. Its light weight for a given power with resulting low first cost and capital charge, the low costs for foundations, the high speeds with consequent low costs for connected generators, the small space required and the simplicity and economy of operation are important reasons for suggesting new fields for this prime mover, which has been proven of practical value in a long series of tests under working conditions. The compound engine is especially adapted for use for auxiliary or stand-by service in water-power stations or for carrying the peak loads in central stations where installations are as large as 21,000 kva. have been contemplated. The important considerations are quick starting, non-deterioration of fuel reserve and flexibility of required fuel, amounting to almost complete independence of fuel quality. Other uses for the compound which readily suggest themselves are city water works and irrigation projects, either directly or by electrical distribution.

The possibilities of the compound-Diesel-electric locomotive should not be overlooked, as it presents all the well-recognized advantages of electric traction. At the same time it represents a component part of the central power station, with the advantage over the latter that it operates at the highest thermal efficiencies known—nearly three times the efficiency of even a very large power plant, i.e., three times the tractive effort is delivered to the rail from every pound of fuel burned. Also the capital charges for main feeders, substations, bonded rails and shunted switches and frogs, and the third rail or elaborate overhead construction are eliminated. The tracks are used exactly as they now stand.

Application to Ship Propulsion

We now come to the greatest present employment of oil engines, namely, their substitution for steam in ship propulsion. The advantages of motorships are rapidly being recognized, and they are now being built in practically every maritime country more rapidly than ever before. There were building last year 454,502 tons of Diesel-driven ships, or over 7 percent. of the world's total under construction. In the light of the past ten years' experience the Diesel engine has proved an efficient, reliable and thoroughly seaworthy prime mover, suitable for a large proportion of the total sea-borne tonnage.

Novel Electromagnetic Clutch Affords Elastic Drive

In connection with the development of the compound engine for marine purposes, and in order to provide any Diesel type of engine with speed flexibility equaling the reciprocating steam engine, there has been developed an electromagnetic clutch operating on an entirely new principle.

This new type of clutch transmits power entirely through air gaps and has no mechanical contact whatever between the driver and driven, eliminating wear and deterioration. It is capable of remote control and can be operated at any speed from zero to full engine speed; the torque may be varied at will from maximum to minimum. The power required to operate the clutch at full load is but a small fraction of one per cent. of the power transmitted. In one instance 525 hp. required 256 watts, or 0.065 per cent of the power transmitted. An outstanding feature of this clutch is that on direct drive or full speed it is magnetically locked, which insures perfect synchronism and no slip with an extreme increase in pull-out torque. At this and all times, in fact, the transmission has the "velvet touch" of an air drive and insures complete torque-wise isolation of the mass moments lying on the two sides of the clutch. As seen in Fig. 11 the clutch forms a part of even a small-sized flywheel of either a Diesel or compound with little, if any, alteration of its mass moment.

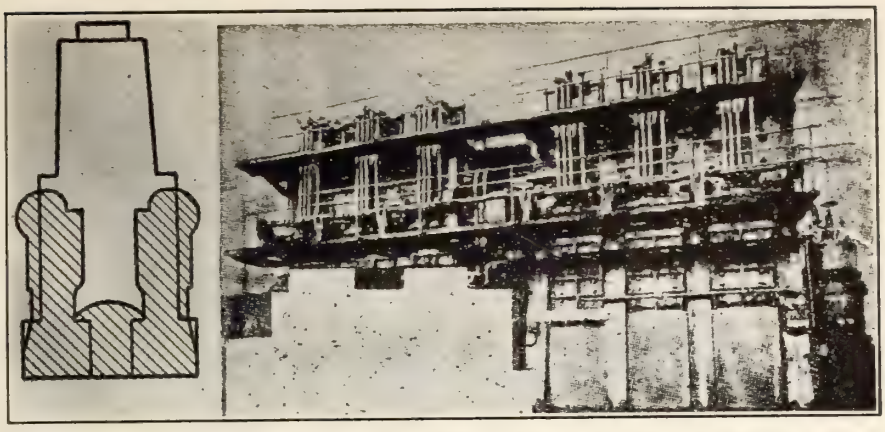

Fig. 13.—Comparison between compound divided unit geared drive and standard Diesel engine delivering to tail shaft and same power and speed.

The clutch is characterized by two kinds of torque operating by opposite phenomena; the greater the differential or relative velocity between the driver and driven parts, the greater the torque available for starting and for bringing up to synchronism. This phenomenon also provides for slipping and continuous operation at all fractional speeds by means of the loaded secondary effect acting as an induction motor.

The air-gap clutch drives through magnetic flux comprising four ring elements, two of which are driving and two of which are driven. The flywheel proper accommodates an exciting coil producing the magnetic flux. At all fractional speeds or while this clutch is slipping, this magneto induction generates large currents in the driven elements which are now acting as short-circuited secondaries, producing heavy drag torques under perfect control by varying the amount of coil excitation. However, when the speed comes up in the vicinity of synchronism, locking occurs.

Proposed Installation of Propelling Machinery

Fig. 12 shows in plan view a proposed installation of the propelling machinery, securing the advantage to both engine and tail shaft of entire freedom of each to run at its own best speed. A propellor for a given ship has a speed at which it gives its most efficient performance; likewise a combustion engine can be built most economically and to give its best performance for a given size if the designer is given entire freedom to choose the best engine speed, a condition which is extremely desirable.

With this clutch and the engine combination shown in Fig. 1 several very important advantages are secured:

(a) There are available on a single propellor all the advantages and flexibility of a multiple engine equipment, where one engine may be shut down and completely disconnected for inspection, valve grinding, etc., and yet the ship be going forward at three-quarters its normal speed.

(b) Complete flexibility of the electric drive without the expense, weight and space of the electric generators and motors and the cumbersome electric control equipment for handling the heavy currents in maneuvering, and the double losses of generators and motors which are of substantial amount and a constant drag on plant and fuel economy.

(c) The simplest form of gear drive may be employed because the magnetic clutch allows the pinion to be a complete "floater." The pinion may thus accommodate itself to any part of precision and all sorts of idosyncrasies of the main gear and teeth without shock. Any irregularities existing have to deal only with the small masses of the pinion itself and its sub shaft, being completely isolated from the large mass moments of the engine.

(d) The well-known irregularities in torque of any reciprocating engine and circumferential oscillation are entirely smoothed out by the air gap in the clutch and are not permitted to reach the pinion; its specific tooth operation is thus completely safeguarded. The crash and general irregularities of the engine torques thus never reach the pinion and therefore can have no effect on the complete smoothness of its performance.

(e) The torque, being under complete control, can be lowered so as to safe-

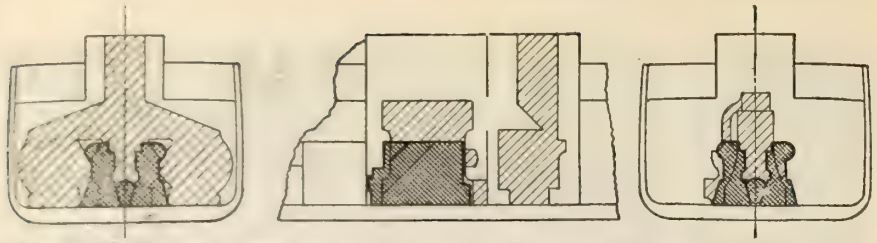

Fig. 14.—Comparison between reciprocating steam plant and geared compound Diesel engine.

guard the equipment against overloading, especially when sailing in obstructed harbors, near derelicts, and where floating obstacles are likely to be encountered by the propeller blades, thus providing an important emergency disconnecting gear breaking away from the large engine masses and allowing the propeller to "stop in its tracks" through the self-interruptibility of the magnetic clutch when reduced to fractional underload condition. In this way many disasters to the propelling machinery and interruptions to the service may be avoided.

(f) Nearly all revolving machinery is subject to periods, sometimes running into severe "criticals." These criticals always develop from the irregularities in torque of the mass moments within the engine pitted against outside mass moments aft. This can occur only when these are solidly coupled with each other, but if instead they are isolated, as by the cushion or air gap of a magnetic clutch of proper design, these troublesome criticals with their excessive stresses are completely suppressed and can never develop.

(g) The combustion engine is reversible and runs equally well in either direction. The magnetic clutch solves completely all maneuvering problems, and in this way stands out in bold contrast to the difficult maneuvering and reversing conditions introduced by the non-reversible turbine.

As seen in Fig. 12, a Kingsbury or equivalent thrust bearing may be located forward of the main gear. The pinions flanking the gear on either side are not necessarily diametrically disposed. This gives an excellent distribution of the machinery, compact engine-room arrangement, and ample space for the small oil-engine generating sets for the ship, which incidentally also supply the clutches with the very trifling amount of energy and any other auxiliaries outboard of the engines. The engines are completely reversing and self-air starting, and either engine may be completely isolated at will. When either engine is running, the other may be gradually or quickly started up by means of the clutch instead of by air, if desired. The engines under this arrangement run with extreme smoothness and under complete control. In one instance the clutch succeeded in suppressing entirely a very serious "critical" which occurred in a 700-hp. submarine type Diesel near the normal running speed.

Saving in Weight and Space over Diesels

In Fig. 13 there is shown in side elevation to the left, and end elevation to the right, the comparison between the compound divided-unit geared drive delivering to the tail shaft the same power and speed as the standard Diesel unit of the largest manufacturer. The divided unit consists of two engines, each with four combustion cylinders, in two compound units. Note each of these engines gives the same turning moments and torque diagram as an eight-cylinder Diesel. In fact, with this divided unit we have eight combustion cylinders in the two engines with less than half of the cams, etc., of a six-cylinder Diesel, with all the advantages of two engines, including immunity from shutdown, possibility of inspection and other operating advantages which are well recognized. These two views serve graphically to give some idea of the saving in weight and space.

To aid in the comparison with the reciprocating steam engine, Fig. 14 has been developed, giving three views of the steam plant in shaded background. Against it there is outlined the standard compound, two-engine, geared magnetic-clutch arrangement for the identical horsepower and speed at the tail shaft.

ANNOUNCEMENT

Messrs. Edwardes Costello & Lowe have opened an office at 772 Bathurst Street, where they will carry on a general engineering business, including feed water treatment, combustion, boiler cleaning services, and general efficiency work.

COAL SAMPLING APPARATUS

Work on the development of new types of coal sampling apparatus is being done at the Washington, D. C., office of the Bureau of Mines, under the direction of O. P. Hood, chief mechanical engineer. The practicability of coal inspection on a large scale depends upon the development of sampling devices which can obtain a true representative sample with the least possible interference with transportation methods. This means the development of apparatus somewhat comparable with apparatus used for loading and unloading coal. A machine has been developed which will drill a six-inch hole vertically through coal carried in a car and abstract the cuttings. Complete detailed plans have been made for a single sampler adapted to take sample from truck loads at the Government Fuel Yard. General plans have also been developed for a multiple sampler adapted to take samples from open top cars in a railroad train without distributing the train or the unloading coal. Only the reduced laboratory sample is to be taken from the sampler.

* * * *

CLEANING COAL.

The past work on the float-and-sink method of cleaning coal, conducted at the Northwest Experiment Station of the Bureau of Mines, Seattle, Wash., has resulted in the development of an efficient large-sized machine for making these tests. This machine has been used in studying the washability of coal, in controlling the washing operation, and for measuring the efficiency of the individual coal-washing machines. In using this machine for future studies, there is a possibility that it will be developed even to a more efficient point. This machine, however, does not give satisfactory results using fine sizes of coal. Work is being planned in which the limitations of the float-and-sink method on fine sizes will be determined. It is hoped that the float-and-sink machine can be adapted to washery control in the coal washeries of the State of Washington.

* * * *

FUSIBILITY OF ASH.

A thorough survey of the fusibility of coal ash from various coals of the United States has been completed by the Bureau of Mines and the data tabulated for publication as a bureau bulletin. The method for fusibility of coal ash as developed by the bureau has been adopted as a tentative standard method by the American Society for Testing Materials. An alternate rapid method known as the micro-meldometer method has been proposed. The bureau has assembled the equipment for this alternate method and in co-operation with a number of other laboratories a series of tests comparing the two methods is being made. In co-operation with the fuel section of the bureau, it is proposed to investigate the relation of laboratory fusibility tests to clinker formation in burning coal under actual operating conditions.

* * * *

TRENT PROCESS FOR CLEANING COAL

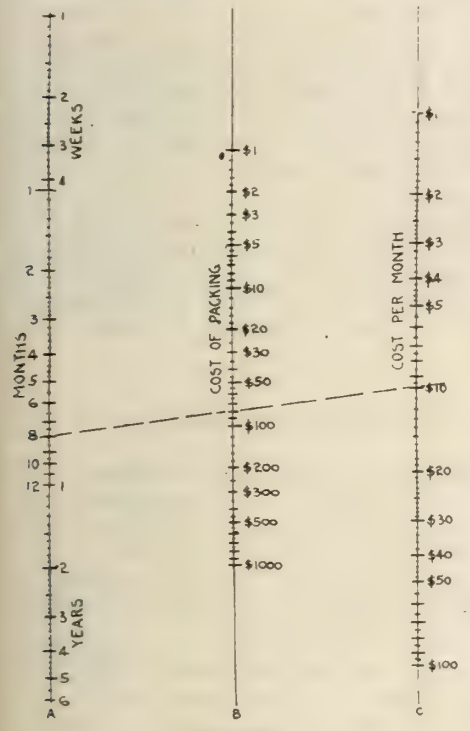
The efficiency of the Trent process in cleaning coal has been determined by the Bureau of Mines for typical coals of the United States. The point of superiority of the Trent process over ordinary washing methods is the high combustible recovery obtained, in some cases as high as 99 per cent. Low-grade subbituminous coals and lignites do not respond readily to treatment by the process. The process is not efficient in removing sulphur present as purite in the bituminous coals; with anthracite coals, sulphur removal is good. The relation between fineness of grinding and ash separation has been determined on typical coals pulverized to sizes as small as 10 microns, (.10 mm.)

HANDY CHART FOR COMPARING COSTS

Copyright by W. F. Schaphorst

This chart will be found handy for determining the cost per month of the various materials used in and about the engine room. It is a good thing to keep tab on supplies purchased so as to know when bought and when replaced. Then by dividing by the number of weeks, months or years of service, the cost per month is found and the engineer can decide whether or not to purchase the same thing again.

For example. Let us assume that a certain engineer bought what he thought was a good trade of packing. He packed his pumps with it, and found the total cost to be $80. After eight months the packing was worn out and had to be replaced again. What was the cost per month? That is an easy one and can be done mentally, but just to show how the chart works, I have selected an easy one for a starter. The dotted line drawn across the chart shows that you merely have to lay a straight edge across connecting the $80 (column B) and the 8 (column A) and the extension of the line



Cost Chart

cuts column C at $10. In other words the packing costs $10 per month.

The engineer now sees a given packing advertised which, it is claimed, will last much longer, but its first cost is more. He might naturally say to himself without figuring at all, "That costs too much. I can't afford it. Guess I had better use the same old packing." However, the engineer leisurely lays a straightedge across connecting the claimed length of life (two and one-half years) with the estimated cost ($200) and he finds to his surprise that such a packing would cost him a trifle over $6.50 per month. He rubs his eyes. He tries again. He thinks there must be something wrong with the chart, and "dopes it out" longhand only to find that the chart, after all, is pretty accurate. As a result he purchases the packing which costs more at first, but considerably less in the long run. It is evident, therefore, that the chart is a valuable one and it would be well to keep it in a handy place whenever looking through advertisements or whenever purchasing supplies.

The chart applies not alone to packing, but to anything that wears out in a short time. Gaskets, cylinder oil, belt treatment, belts, valves, grate bars, etc., all come under this head. Even though the exact cost may not be given in column B it is a simple matter to shift the decimal points in such a way that the correct answer will be obtained in column C. Thus if you bought only three cents worth of waste, and if it lasted four weeks, you would connect the four (column A) with the $3 (column B) and the line cut through the $3.50 in column C. It is evident that in writing three cents with a dollar sign in front of it, it becomes $.03. The decimal point is, therefore, shifted two places to the left in column B, and at the same time the decimal point must be shifted the same number of places to the left in column C, which gives us 3½ cents per month as the answer. The range of the chart, it will be noted, is wide enough to care for every ordinary case of supply purchasing.

W. F. Schaphorst.

New Air-Cooled Motor Cycle Engine

The design of engines for motor cycles presents many problems of interest to the engineer and of great importance to the manufacturer. Simplicity, robustness, reliability, smoothness of running, efficiency, and many other qualities have to be combined in a machine which must in the end be cheap. Mainly because of this last factor, many refinements employed in the motor car engine cannot be adopted in the motor cycle engine. Such conditions offer a clear stimulus to the skilful designer, and a new type of engine produced by a British firm marks a considerable advance towards the ideal. It is an air-cooled motor-cycle engine with sleeve values. Hitherto the use of the sleeve valve in any type of motor car engine has been looked at a little askance, owing to expected trouble with lubrication and cooling. These troubles are not encountered in the numerous examples of automobiles fitted with sleeve-valve engines; and their success has led this firm to adopt the sleeve-valve in an air-cooled engine—the first time this combination has ever been attempted. One great advantage of the sleeve valve is its silent action; the public will be grateful for any reduction in the noise made by motor cycles.

PHYSICAL TESTING OF COKE

The physical characteristics of coke is a matter of great importance to the blast furnace and foundry men. Tentative definitions of terms relating to coke have been formulated by the Bureau of Mines and submitted to the American Society for Testing Materials. Data are being assembled as to the methods in general use in making "shatter" and "hardness" tests on coke. The Bureau of Mines realizes that if the results of such empirical tests are to the best advantage they must be standardized in order that the results obtained be comparable. It is proposed to get as much information together as possible as to the methods of conducting these tests and from these data tentative methods will be submitted to the American Society for Testing Materials for the making of "shatter" and "hardness" tests on coke.

SPECIFIC GRAVITY STUDIES OF COALS

Preliminary to undertaking a detailed investigation of the different coal washeries in the State of Washington, a study has been made by the Bureau of Mines of the specific gravity and ash content of many Washington coals and their associated impurities. Results of this study indicate that both the coal and the impurities as they exist in the bed are saturated with moisture. A technical paper describing this study is now in preparation.

ORIGIN AND CHEMISTRY OF COALS AND SHALES

An extensive investigation is being conducted by the Bureau of Mines regarding the origin, composition and chemistry of coals, cannel coals and boghead coals. The coals from various beds and localities are examined microscopically. Thin sections are cut and examined at all magnifications; the constituents forming coal are examined and certain characters are recorded photographically. Coals may thus be studied concerning their nature, quality and various characteristics. The kinds, relative amounts and nature of the various constituents are studied and co-related with their distillation products and other qualities and characteristics shown in relation to their economic uses, such as coking, gas production, steaming, etc. Oil shales and cannel slates are also being studied by the Bureau of Mines as to their origin, composition and chemistry. Thin sections are cut and studied under the misroscope and characters recorded photographically. The mineral matter is removed by means of acids and the remaining organic matter examined and compared with thin sections. The organic matter is burned out at low temperatures and the remaining mineral matter also examined and compared with thin sections. The kinds, nature and relative amounts of the various constituents are thus studied and co-related with the kinds, nature and relative amounts of distillation products.

The report of the investigation made by the Bureau of Mines at the Pittsburgh Station, relating to the value of coke, anthracite and bituminous coal for the generation of steam in the low pressure cast iron boiler, is being prepared for publication at a later date.

The Board's Circular Letter

IN ANOTHER part of this issue we reprint a letter that has been sent to the chairman of the Board of Stationary Engineers, to manufacturers and those who own plants coming under the jurisdiction of the department.

It is noteworthy that a number of our readers have sent this letter to us, with favorable comment, and a request to publish it, which we had already decided to do, feeling that it should be seen by as many engineers as possible.

The spirit of the letter shows a nice appreciation of the view point of both engineer and employer, their claims on each other. It points out that the way for the engineer to make himself more valuable is for him to increase his education and knowledge. It shows that the Board of Examiners are anxious to give the man who is still in the lower grades a chance, and are making the examination for the lower grade certificate of a practical nature. A feature that should be re-assuring to everyone is the distinct statement that there are no "catch" questions. Mr. Brown is to be congratulated on his action in sending this letter out, and the appreciation of the possibilities of his position that it shows. The engineers are also to be congratulated on the fact that it is quite evident that in the chairman of the Board of Engineers they have a fair minded official who is anxious to do the right thing by all parties concerned.

It remains now for employers in general to help on the good cause by making the engineer's position one that will attract the best type of man, and make it worth his while to spend his time in study to make himself a better man. When all is said, the person who derives the most benefit from the better education of engineers is the owner of the plant, and he should recognize this fact, and act accordingly.

Another Step Forward

THE DESCRIPTION of the compound internal combustion engine in this issue of "Power House," should be read eagerly by the engineering profession. The development of this engine marks another step forward in the eternal endeavor of man to utilize the forces of nature with a greater degree of efficiency.

The utilization of the energy remaining in the gases in the cylinder of the internal combustion engine, at the moment exhaust ordinarily takes place, enables great economies to be effected, not only in fuel, but in space and weight of the engine. In fact, it is stated that a weight approximating five lb. per horse power is attainable. The inventor of the engine points plane engine, that is, making it possible for the heavy oil engine to be used for aeroplanes, eliminating the fire risk from the gasoline tank.

While this particular engine has been developed for marine use the principle lends itself to stationary application just as readily.

Experimental work is being carried on in England with the Still engine, in which the hot exhaust gases from the internal combustion engine cylinder are passed through a small boiler or regenerator and the steam obtained is used on the under side of the engine piston. The device is not so simple as this brief description would indicate, but the thermal efficiency achieved has been very high. In this engine the water cooling effect of the jacket is increased by allowing the water to be evaporated, thus utilizing the latent heat property of the jacket water. At thermal efficiency of 39.2 per cent. has been achieved with this engine.

The time must come, and perhaps it will come more speedily than some of us think, when the practice of burning coal in its raw state under boilers for steam generation will cease altogether. It is universally known to be highly wasteful, not only in the loss of heat, but the loss of valuable by-products, which are carried away with each pound of coal burnt in boiler furnaces.

The continual research and experiment that is going on, and the startling developments which come as the result of these investigations, keep the engineer keenly on the alert, so that he may be abreast of these developments, and ready to seize the opportunities that may be presented to him by them.

Pay as Promptly as Possible

FINANCING is not an easy matter just at present. In fact, some firms frankly admit that the reason they cannot pay their bills as promptly as they would like to, is because they in turn cannot collect from their customers. Unfortunately some who do not really need to do so, are taking advantage of the situation, and are issuing notes, and retarding the payment of same as long as possible.

When any number of firms start this practice, it is not long before the majority of the business community is following suit, financing on long terms instead of prompt acceptances. This is bad business, and while every leniency necessary should be extended to worthy institutions, who may be rather pressed for ready cash at the moment, still, on the other hand, no financially able firm should hold back payment when they are able to pay their way. Let a few of this type start the ball rolling, and it would not be long before collections would become easier all around.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

BOILER DIMENSIONS AND EVAPORATION

Question:—Please give the principal dimensions of a 60 inch by 20 feet long h.r.t. boiler. What rate must water be evaporated per horse power? If a boiler evaporates 2987 lbs. of water from 100 degrees into steam at a pressure of 100 lb. gauge per hour, what is the equivalent evaporation from and at 212 degrees? G. K.

Answer:—To answer the first question it is necessary to make some assumptions. In the first place no pressure is given for the boiler, and secondly, twenty feet would be a most unusual length for a boiler of this diameter. It would more likely be 16 feet or perhaps 18 feet. We take it that the questioner requires thickness of plates, number of tubes, etc. If we assume to begin with that the boiler is to work at 100 lbs. per square inch, and that the longitudinal seam is to be of at least 75 per cent., we can get the thickness of shell and heads, area of segment, number of stays. The formula for working pressure is

$$W.P. = \frac{T.S. \times \% \times 2t}{F \times D}$$

where T.S. = Tensile Strength of material
% = Least % of longitudinal seam
t = thickness
F = Factor of safety
D = Diameter of boiler in inches.

Allowing that the tensile strength of the material will be 60,000 lbs. per square inch, and that the boiler has a factor of safety of 4.5, we can from the above formula find the thickness of shell.

$$t = \frac{W.P. \times F \times D}{2 \times T.S. \times \%}$$

substituting figures for the letters in the above

$$t = \frac{100 \times 4.5 \times 60}{2 \times 60000 \times .75} = .3$$

This gives us a thickness of shell plate of .3 inch. Now as plates are made in thicknesses varying by sixteenths of an inch we must see what is the closest dimension in 1/16ths corresponding to .3. Then we have .3/.0625, which is 5/16ths.

We have then 5/16ths for the shell, and allowing 1/16th more for the head we shall have 3/8th heads. Allowing one third of the volume of the boiler for steam space that gives us a height of 24 inches for the segment, assuming that there will always be four inches of water over the top of tubes. A boiler this size would be approximately 75 horsepower, which gives a heating surface of 1125 square feet. If the shell is 16 feet long then the heating surface of shell will be

2.5 x 3.1416 x 16=125.6 square feet.

This leaves approximately 100 square feet to be supplied by the tubes. The heating surface of one tube is the outside diameter x 3.1416, divided by 12, and multiplied by the length, so if we take a three inch tube we have

$$\frac{3 \times 3 .1416 \times 16}{12}$$

12.5 square feet in one tube.

This would give a total of 80 tubes. Of course in laying out the tube sheet for actual construction there might have to be some modification of this, but these would be the dimensions which would determine the design. The area of segment can be found after the actual tube sheet is laid out by the rule

$$\frac{4x \; hxh \; x\sqrt{\; d}}{3 \qquad h} .608 = \text{area},$$

making the usual allowances for tube and shell support.

After the area of segment is determined the number of stays and their diameter can be found. The total load on the segment will be the pressure x area of segment. This divided by the stress per square inch allowed on the stay material will give the total sectional area of all the stays. The number of stays can be determined by the minimum pitch which will allow for free movement in the boiler, and this pitch divided into the total area to be supported will give the number of stays. Knowing the number of stays and the total sectional area of stay required, the area of one stay can be found by dividing the number of stays into the total sectional area. The joint on the longitudinal seam would be a double riveted lap to fulfil the 75 per cent. that we assumed. If a triple riveted lap or a double riveted butt joint is used they can be designed to meet the requirement of a minimum ratio of 75 per cent. to the solid plate.

A study of the issues of Power House for the latter part of 1920 will give the reader full particulars of this matter. We have not space here to go fully into this.

A boiler horsepower is the evaporation of 34½ lbs. water per hour from and at 212 degrees, that is from water at 212 degrees into steam at 212 degrees. Steam at 100 lbs. gauge has a temperature of 337 degrees, and with feed water at 100 degrees this gives a quantity of 227 B.T.U. per lb. to raise the water to the same temperature as the steam. The latent heat of steam at 100 lbs. gauge is 876 B.T.U. so that we have a total quantity of heat of 876 plus 227 or 1103 B.T.U. required per lb. steam. As the quantity of heat required from and at 212 is only 966, the factor of evaporation would be 1103/966, which is 1.14. Multiplying 2987 x 1.14 we get 3405.18 lbs. as the equivalent evaporation from and at 212.

PLANT RATING AND BOILER FEEDING

Question.—In the case of a battery of two boilers connected up together, each carrying 100 lbs pressure, what would be the rating of the plant, two hundred or one hundred horsepower? R. I.

Answer.—The rating of a boiler for the purposes of the Ontario Act is independent of the pressure carried, but is calculated on the heating surface. The rating then will be proportional to the total heating surface of the boilers in the plant, and two boilers each rated at 100 horsepower would be a two hundred horsepower plant.

Question:—If a battery of three boilers is fed by a feed pump and one boiler is cut out of the line, and allowed to drop to 50 lbs pressure, would there be any harm in feeding it with the same feed pump that is feeding the other two boilers at 100 lbs pressure? Would the pressure be equalized if all three valves were opened at the same time? R. I.

Answer.—Opening all the checks to feed would not have the effect of equalizing the pressure on the boilers, the only result would be that all the water would be delivered to the boiler having the least pressure. If all the steam valves from the boilers to the pumps were opened the pressure would then be equalized, but on the feed lines the check valves would prevent the pressure from the 100 lb boilers blowing back to the 50 lb one, unless these checks were lacking. In feeding the low pressure boiler the steam valve on the pump would have to be checked or else the pump would be likely to run away, causing shock and perhaps damage to the pipes.

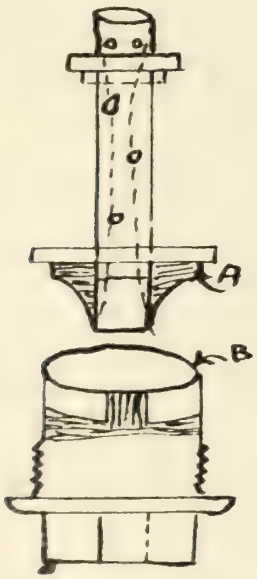
Continued on page 45

The Operators' Point of View

AN INJECTOR TROUBLE

The accompanying sketch of the jets of a ¼-inch injector will serve to explain the following:

The injector was supplying a 50-horsepower boiler, supplying steam to a Waterous engine, and never gave any trouble until recently, when it commenced overflowing considerably, and only feeding about half the water it picked up. There was no sediment in the feed pipe, and no apparent cause for the trouble.



Injector Jets

I took the jet apart and fitted a gasket about 3-16th thick in between the two at the flange A, and screwed them together again, after which there was no further trouble. I have since found that a gasket 1-16th thick will do the same.

This may be of interest to other engineers.

BOARD OF ENGINEERS

In sending out the copy of the amendments to the act passed at the last session of the legislature, the Board of Examiners are enclosing the following letter, to all manufacturers and owners of plants coming within the regulations. The letter is a statement of policy, and as such, should be of interest to the engineers as well as the owners.

Dear Sir.—In order that you may become familiar with the amendments made to the act respecting stationary and hoisting engineers at the last session of the Legislature, we are enclosing, herewith, a copy of the act. We particularly wish to draw your attention to the section dealing with the requirements demanded by the Board of the different classes of engineers.

The engineer believes that, owing to the responsibilities placed upon him, he should receive higher remuneration than the ordinary laborer, but we also believe that it is the duty of the engineer to fit himself for these responsibilities and put forth his best efforts to obtain the knowledge that will enable him to efficiently and safely perform his duties.

Ambition is the keynote to success and we believe that graded certificates will encourage the engineers to rise to the height of the profession. In their endeavor to reach this height they must constantly be in search of new knowledge which they will unconsciously apply in the daily discharge of their duties —thereby making themselves of greater benefit to their employers.

We endeavor to make the questions presented on the lower grade examinations papers of a thoroughly practical nature, dealing with the construction, care and operation of all apparatus found in the ordinary Ontario power house, with which every energetic engineer will be familiar. We are careful to avoid all catch questions.

It is our aim to encourage the engineers to become more observant of the different apparatus found in their own plants, and to study the articles which may be found in the many excellent books, magazines, and pamphlets now published on engineering work. We also advise that when possible he take advantage of the night school classes for engineers, nearly every large centre in Ontario having one or several of these classes.

We ask your co-operation and assistance, and we will at all times be pleased to have your suggestions and criticisms.

Yours very truly,
J. M. BROWN, Chairman.

BOILER PLATE FAILURE

By C. H. Watson

Power House readers may be interested in the particulars of a failure under hydraulic test which took place recently, on a boiler built in 1911 while under a hydrostatic test of 160 lbs. per square inch. The boiler is a horizontal return tube of 66 inches diameter by 16 feet long, with a shell 7/16th inches thick. The shell is made from two plates, the longitudinal seams being triple riveted lap joints. The working pressure allowed the boiler was 130 lbs. per square inch. Under the hydraulic test the second plate gave way along the edge of the rivet heads. The plate is eight feet long, and the split extended for a length of about six feet, to within about four inches of the back head. In the centre of the fracture it opened up about 3/16th inches, and revealed the fact that there was only about 1/32nd inch of the original plate left in one part extending about the length of four rivets. This crack could not be seen from the inside as the under plate covered it by about 5/8th inch. As far as the writer knows this is an unusual place for fracture.

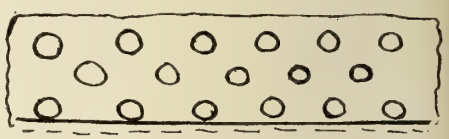


Plate Fractured under rivet heads where black line is drawn above dotted line.

The boiler appears to be in good condition otherwise.

Editor's Note.—There have been a good many instances of fractures of this kind taking place with lap joints, and for this reason this type of joint is looked on with great disfavor by a good many authorities.

NOTICE TO CORRESPONDENTS

Power House wishes to express thanks to those correspondents whose letters have arrived since last issue of Power House, on the question of the Dominion-wide Certificate. We believe that this correspondence has achieved its object, and have therefore terminated it. To those whose letters did not receive publication we would point out that it was not possible to publish all the letters received, through lack of space, but we endeavored to show as many viewpoints as possible.

Our columns will be open to anyone coming forward with a concrete suggestion as to how best to obtain action leading towards the establishment of this certificate, which seems to be approved of by the large majority of our correspondents.

The York Sandstone Bridge Co., East Toronto, Ont., is asking for prices on a horizontal tubular boiler.

C.A.S.E. Competition Questions and Answers

Question:—What is CO_2 and why is CO_2 percentage accepted as an indication of combustion conditions?

Answer.—CO_2 is the result of the perfect combustion of one part carbon and two parts of oxygen. CO_2 percentage is taken as an indication of perfect combustion condition because when carbon is burned on a grate there is an action taking place as follows:—The oxygen passing through the grates as air combines with the hot carbon in the proportion of two (2) of oxygen to one (1) of carbon forming carbon-dioxide, and as long as the air is sufficient this condition of chemical action is maintained. The combination or product of combustion is called CO_2. If the fire bed is too thick or has holes in it for the admission of excess air the combustion or result would not be perfect combustion and the product is called CO or carbon monoxide and this gas in excess indicates that the combustion is imperfect and the maixmum amount of heat has not been developed from the fuel.

* * * *

Question:—What is a CO_2 recorder, and describe the operation of at least one well-known make?

Answer:—A machine which automatically analyses the flue gases to give the percentage of carbon-dioxide, the chemical symbol of which is CO_2 from which fact the machine is known as a CO_2 Recorder. The Orsat consists of a combination of collector and three graduated glass tubes, containing various chemical solutions. Each tube contains an obsorbent solution; one to absorb CO_2; one for CO, and one for O. Each part has a small "U" shaped pipe attached and they are half-filled with their respective solutions; the CO_2 pipe has a solution of caustic potash and pyrogallic acid; the CO pipe has cuprous chloride in it, which is from copper oxide 25 grams and 500 c. c. of hydrochloric acid, and reduced by adding an equal volume of the acid mixture. Water well saturated with CO_2 is used for displacement but for very accurate work it is better to use brine water or mercury.

* * * *

Question:—(a) Explain why 21% CO_2 is the highest possible percentage in flue gas. (b) What are the component parts of flue gas.

Answer:—Because the air or draft is composed of 21 parts oxygen and 79 parts nitrogen, and as carbon will only combine with the oxygen therefore the amount taken from the air cannot exceed 21%, except where some artificial gas is introduced along with the air, as in the case of blast furnace gases.

(b) Oxygen ....Symbol	O
Nitrogen	N
Hydrogen	H
Carbon monoxide	CO
Carbon dioxide	CO_2
Sulphur	S

Question:—Why is it that 21% is not the most desirable? Give calculations proving this and supply if possible a simple formula to determine this point.

Answer:—One thing could be said and that is that there might be an excessive temperature accompanying 21% CO_2 and this would ruin the brickwork by over expansion, thus causing cracks, etc., besides excess stack or exit gas temperatures would indicate heat losses, offsetting the CO_2 indications.

* * * *

Question:—What percentage of excess air is present 8, 9, 12, and 15% CO_2?

Answer:—In dealing with the problem we have assumed that we are dealing with pure carbon and not ordinary coal.

$$\text{Formula:}\quad \frac{21-CO_2\%}{CO_2\%} \times 100 = \text{excess air}$$

$$8\%\ CO_2 = \frac{21-8}{8} \times 100 = 162\%$$

$$9\%\ CO_2 = \frac{21-9}{9} \times 100 = 133\%$$

$$12\%\ CO_2 = \frac{21-12}{12} \times 100 = 75\%$$

$$15\%\ CO_2 = \frac{21-15}{15} \times 100 = 40\%$$

* * * *

Question: — What is the correct method of regulating air supply to furnace and why?

Answer:—By a damper in the breeching or smoke-box because when the air supply is regulated by the ash-pit door, it is liable to cause the air to come through the openings or cracks in the brick-work, and the cooling effect of the air passing up through the grates prevents their being warped or burned.

* * * *

Question: — Assume a hand-fired furnace with a CO_2 recorder connected indicating a drop from 15% is shown. Give probable reasons for this record step by step.

Answer:—Too thin a fire or "holes," spots burned out; the further drop in CO_2 to 4% is caused by opening furnace doors or the time taken to spread the fire evenly to cover the holes, etc.; and after the green coal or fuel has been added, and as the temperature rises the oxygen unites more perfectly with the carbon and the CO_2% rises to 15%.

* * * *

Question:—Describe what is known as the balanced draft system. Give reasons for and against this system.

Answer:—Balanced draft is a condition where the pressure under the grate-box is equal to the draft over the fire. The condition is obtained by use of force draft under the fire.

* * * *

Question:—Describe the operation of an automatic damper. Give reasons for and against from strictly combustion point of view.

Answer:—An automatic damper operates through the action of a lever lifted or controlled by a diaphragm-valve combination where the motion of the diaphragm subject to variations of steam-pressure is transmitted to the lever which is connected in such a way as to open the damper as the pressure goes down and to close the damper as the pressure increases; however as a rule through lost motion and other frictional losses they are slow in opening the damper and also in closing the damper resulting in higher pressures than are needed and the safety valve blows, thereby causing a serious loss of steam or its equivalent in heat units. Further when the opening is delayed and the boiler pressure is still falling the CO_2 from a combustion point of view is also low. Some manufacturers claim to have made a damper regulator which is free from loss of motion and which will regulate to a pound per sq. in. of the variation of the steam pressure carried.

* * * *

Question:—Give description of a system of combustion control by steam flow, and give reasons why, in your opinion, this method is theoretically correct.

Answer:—In this system of combustion control, the difference in pressure on either side of a venturi-tube is taken advantage of. The tube is introduced in the path of the main steam flow and the slightest change in flow is registered and acts upon an intervening balance-control which in turn acts upon the damper and air admission; also in the case of a mechanical stoker it regulates the rate of coal feed and depth.

WATER GAUGE GLASSES

Gauge glasses frequently break and must be replaced. This is an operation that requires much care and, in this regard, we believe that no better information can be found than that given in an article entitled "Water Gauge Glasses," by Charles S. Blake, now president of this company, which was published in the January 1912 issue of the "Locomotive." Because of the valuable information contained in that article, we are reprinting it herewith.

"The breaking of water gauge glasses is of such frequent occurrence, that a few words concerning their attachment and use may, if heeded, prevent some accident and possibly personal injuries, besides the annoyance of frequent replacements.

"The use of a visible gauge as an auxiliary to indicate height of water in a steam generator has become a recognized necessity, and is required by authorities exercising jurisdiction over boilers. One municipality at least places such

value on their use as to recognize a second gauge glass as a substitute for the gauge cocks and does not require the latter when two gauge glasses are properly affixed.

"The ordinary or customary gauge glass is a plain cylindrical tube, ranging for ordinary use from ⅝ inches to⅞ inches in diameter and of a length to suit the varying conditions and types of boilers. These diameters are outside dimensions. They vary slightly, but as the glasses are set in compressible washers such variation is not detrimental. They are made in this country and abroad but those of Scotch glass are considered the best. The very nature of the material makes it brittle, and aside from its brittleness it possesses other peculiar qualities that when known should cause engineers and firemen to handle these glasses with more than ordinary care. A novice in examining a gauge glass will almost immediately pronounce it defective, because of the fine lines running lengthwise in it; but such lines are usually indicative of good quality and are more pronounced in the Scotch glass than in the American.

"All glasses are keenly susceptible to surface abrasions, even so minute as to be unobservable. If one receives the slightest scratch inside or out, it should not be used, and in handling or keeping them in stock, no metal of any nature should be allowed to come in contact with them. They are particularly liable to break if iron or steel touches them, and so should never be laid down even temporarily with tools, as is frequently done in preparation for a renewal.

"It may sometimes be thought desirable to clean an old glass when it has every appearance of being whole and sound. In such an event, waste or a cleaning cloth should be used and should be pushed through the bore by means of a wooden stick small enough to pass without force. As a rule, however, the price of gauge glasses is too low to bother with the cleaning of old ones, and if one shows any deterioration at its ends, is should be discarded in any case.

"In the prevention of accidents, not the least measure of importance is to have the receptacles for the glass properly attached before trying to insert it. Every one who has had occasion to put in gauge glasses is familiar with the so-called gauge "cocks," which form its support. They are not cocks, however, but valves. In some of the special types of water glass connections, cocks are used as a means of closing, but the percentage in use is very small. The valves are fitted in various ways,—sometimes directly into the boilerplate, more commonly into water columns of cast iron or those improvised from ordinary pipe fittings. The openings to receive the valves should be parallel and threaded an equal depth, so that when the valves themselves are screwed in position the sockets in them for the reception of the glass will be in a direct line. Both top and bottom valves have these sockets bored out to a considerable depth. If the eye cannot detect the valves out of line, the glass should be inserted in them, to more clearly determine whether the valves are in true alignment or not. The glass should be cut to the greatest length that will permit its insertion, one cock or valve usually admitting it to a greater depth than the other.

"In the selection of a glass, one should be used that will freely enter the valve receptacle and leave a little space around it when in position, and the nuts or glands for compressing the gaskets should be large enough not to touch the glass when screwed up. Only fresh, pure rubber gaskets or washers cut by machine, uniform in size, and prepared for such purpose should be used. After inserting the glass in the valves, it should be shifted so that washers will be at an equal distance from its ends. This is very important, for the writer in his investigations of boiler explosions has found two instances where a washer softened by the heat, under pressure of the gland, has squeezed out under the glass and closed the opening, thus permitting a false indication of the water level.

The glands should first be screwed by hand, each a little in turn until they can no longer be moved by the fingers. Then a small wrench may be used on them alternately, until the glass is firm in the packing. Care should be taken that the glass does not shift in its vertical position, during this operation.

"It may be needless to say that in renewing a glass with pressure on the boiler, the valves should be closed tight and the drip opened to release the pressure before attempting the removal. When a new glass has been put in, if the valves are not provided with means for opening at a distance, a board or sheet-iron shield large enough to protect one's head should be held between the face and the glass, and the valves then opened very easily and slowly to their full extent. When they are open, it is advisable to retire with the shield in front of the face to observe at a distance whether there are any leaks, and if any appear, to return to the glass with the face still protected, shut off the valves, release the pressure through the drip, and then tighten the nuts. Never under any circumstances attempt to tighten them with pressure on the glass.

"In the writer's experience, he has found it possible to make the joints tight by only a slight pressure of the wrench and whenever he has found gauge valves out of alignment he has trued them up. As a result of this practice during considerable experience with marine and stationary boilers never has he had a glass break under pressure.

"If gauge glasses are properly handled and used they will withstand great extremes of temperature, although it is well to guard against drafts from outside in cold weather. In the selection of glasses it is not necessary to pick out the ones with the heaviest walls, for these with slightly lighter walls are as strong and will last as long as the thicker ones.

"The great precaution is to keep the surface from being scratched, for, as every engineer knows, it requires but the slightest breaking of the skin of the glass in a circumferential way to cause it to almost fall apart. The peculiar phenomenon of the glass breaking which has lain next to iron or steel has never been explained to me, but I have a number of times as an experiment, taken a glass, run a smooth rod of iron through it and put it away. Sooner or later it has been found shattered in many pieces. My first observation of this phenomenon was when I placed a glass on a shelf in an engine room with a large pocket knife against it to keep it from rolling off. The next day I found the glass all in pieces, but the pieces in the respective positions, showing that the breakage was not from violence, else the piece would have been scattered."

ENGINEERING NEWS

The New Orleans Association of Commerce has requested the assistance of the Bureau of Mines in an educational campaign looking toward the abatement of the smoke nuisance in that city without necessitating the passage of legislation to accomplish the desired end. The Chamber of Commerce of Akron, Ohio, has also been in correspondence with the bureau regarding an anti-smoke campaign in that city.

The objects of a new investigation being undertaken by the Bureau of Mines at the Pittsburgh experiment station on the determination of composition of gases arising from a thin fuel bed are: by blowing air at known rates through a fuel bed of known thickness, formed from anthracite, coke or bituminous coal, to find out the quantity and composition of the gases above the fuel bed; and so show how much air must be admitted to burn their combustible constituents.

Tests have been made at the Pittsburgh Experiment Station of the Bureau of Mines on the Speller process for removing dissolved oxygen in hot-water heating systems. This process endeavors, by removing dissolved oxygen from the water, to retard corrosion of the hot-water pipes. An instalation has been in use at the Pittsburgh station for about a year. The first test showed that the water heater did not heat the water to a high enough temperature when the most water is being used in the building, so the heater was covered with asbestos and a second test made. The oxygen deactivator proved efficient in removing dissolved oxygen provided the water entering the deactivator was kept at about 170°F. The investigation is being continued.

Cooling Water for Air Compressors

N operating Air Compressors every engineer knows that it is necessary to circulate cold water through the water jacket of the air cylinder to keep it from becoming over-heated, but few have considered what is the most efficient temperature to strive for, that is whether it would be better to have more or less water passing through. Like everything else there is a point where the most efficiency will be gained and while it may not be possible to attain this condition, the knowledge of what is the most economical amount of cooling of the air cylinder enables us to intelligently control the cooling water to gain the highest possible efficiency under a given set of conditions.

At first glance it would seem that whatever heat was carried away by the cooling water was wasted, because this heat having been converted from the energy put into the air compressor all the heat that went into the cooling water represented so much wasted energy, and therefore the less cooling water we could get along with, and still not get the cylinder dangerously hot, the less energy would be wasted. That all the heat transmitted to the cooling water is derived from the energy supplied to the air compressor, and that such disposal of it is wasting the energy is quite true, but as will be explained later on in this article, all the energy in the air that is represented by its increased temperature is inevitably wasted, and it is more economical to remove it from the air as quickly as possible, than to leave it in the air to be slowly dissipated later on.

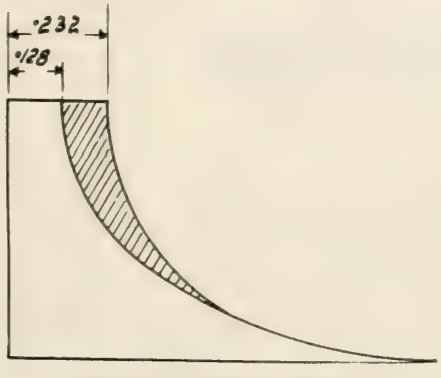
To understand why this loss of the energy contained in the air in the form of heat is inevitable, it is necessary to know what happens while the air is being compressed, and when it is put to work in the air tool. Starting with air at atmospheric pressure and temperature, the whole of the energy used in compressing the air is converted into heat, the foot pounds of energy exerted by the compressor drive being exactly equaled by its equivalent in British Thermal Units added to the air as indicated by the rise of temperature of the air, neglecting friction. In actual practice owing to the necessity for storing the compressed air to meet the fluctuating demand, and because of the length and multiplicity of piping required to carry the air to all the various tools, it is manifestly impossible to retain the high temperature in air, and it practically always fall back to atmospheric temperature before being put to work.

The statement that all the energy used in compressing the air is converted into heat, which is dissipated and lost, seems to be an anomalous one, as if all the energy put into the air is thus wasted, how comes it that the air can still perform useful work after losing all the heat or energy expended upon it? This is explained by the fact that there is energy in the air, by virtue of its containing heat at atmospheric temperature, and the act of compressing it makes this heat available as a source of energy. That is, the air in expanding performs work, and falls still lower in temperature, the heat units given out being equivalent to the foot-pounds of work done.

Obviously the if the air is in any case going to lose the heat gained in compression, there is nothing to be gained by curtailing the amount of cooling water passing through the air cylinder, it beginning in practice to dissipate the heat as fast is it is generated. Coming now to the saving to be gainned by removing this heat as rapidly as possible, if we take a cubic foot of air at atmospheric pressure and sixty degrees temperature Fahrenheit and compress it without cooling to one hundred pounds gauge pressure, it will give us .232 cubic feet of compressed air at 485 degrees temperature. After leaving the compressor it will cool down to atmospheric temperature again, say sixty degrees, and will if kept at the same pressure, contract in cooling to .128 cubic feet. If on the contrary it was possible to dissipate the heat as rapidly as it was generated, and so keep the air at its initial temperature during compression, the cubic foot of free air would be compressed to .128 cubic feet in the cylinder, and there would be no subsequent contraction.

The output from the compressor, that is in cubic feet of compressed air in the receiver at atmospheric temperature will be the same in both cases, other conditions being the same, but when the air is uncooled it will reach the full pressure in the air cylinder when the piston is still .232 of its stroke from the end of the stroke, while when the air is kept cooled to the initial temperature, the full pressure will not be reached until the piston is at .128 of its stroke from the end. The result of this is shown by the diagram herewith, which shows a theoretical indicator diagram for an uncooled compressor, imposed over one for a theoretically perfectly cooled compressor.

The larger diagram represents the first case, and the smaller diagram the latter, and the shaded area represents the additional energy which has to be exerted to compress the uncooled air, over that necessary when the heat is dissipated as rapidly as it is generated, the useful energy made available being the same in both cases. The extra power required is about fifty per cent. of the total needed for theoretically perfect cooling.



Theoretical Indicator Diagram

Of course a compressor is never run without some cooling, as the temperature reached would be destructive, nor is it practicable to remove all the heat from the air due to compression, while the air is being compressed, but this latter condition is the one to aim for, as the economy is increased considerably the nearer we approach to keeping the air at its initial temperature.

While it is usually impossible to keep the compressed air at a temperature any higher than that of the shop in which it is being used the higher the temperature at which the air is used the better, as there will be less heat wasted, and therefore the air tools should be as close to the compressor as possible, and the air piping as short and free from unnecessary ramifications as possible. Obviously the air should never be cooled below the temperature at which it will enter the tools it is to drive, but all the cooling that is possible down to this temperature should be done while the air is being compressed.

If the incoming air to the compressor can be had at a lower temperature than that at which the air enters the tools, the difference in temperature gives a clear gain of available power, as the lower the initial temperature the lower will be the final temperature in the compressor, and hence there will be less heat to be wasted in cooling the air to the temperature of the shop. For this reason the air inlet should always be piped to the coolest point available.

For those exceptional cases where the air is used at a point quite close to the compressor, and the air does not have time to lose its heat in a receiver, or in traveling through long pipes, it is wasting energy to cool the air below the temperature that the tools to be driven will work successfully with. This high limit of temperature may be taken as 300 degrees Fahrenheit.

The water service pipes for air compressors are not usually as carefully laid out as they ought to be. A common fault is to run a main water service pipe past a number of air compressors and connect each cylinder by a branch pipe from this main. This results in the water taking the easiest course, or in other words, short circuiting through the cylinder that offers the shortest or easiest way to the ultimate outlet, leaving the other cylinders with too little water passing through them to be effective. When more than one cylinder is connected to the same main, there should always be a valve at each cylinder to enable the operator to control the division of the available circulating water and divert the main quantity to the cylinders requiring it.

A COMMUTATOR REMEDY

By J. Mendellsohn

Some time ago I took charge of an isolated plant, which had amongst other equipment, two 10 K. W. direct connected D. C. units. These were giving a lot of trouble with sparking and blackening the commutator.

Although I sandpapered the commutator and spaced the brushes, the sparking was getting worse and I had almost reached the point of giving up the job when I remembered having read that boiling the brushes in vaseline might help. I tried that and found to my satisfaction that there was some improvement, but unfortunately it did not last long, and in a week the trouble was just as bad as before.

I again boiled the brushes, but instead of spacing them this time, I set them with the aid of a milli-voltemeter at a point where there was the least difference of potential between the edges of the brushes, and after turning the commutators, the machines ran satisfactorily for six months, after which they only needed sandpapering again.

DESIGN OF DYNAMO

Question:—I want to build a dynamo to carry about twenty lights of 32 candle power. I have built smaller machines of about 1/20th horsepower, but do not know how to go about a larger one. Can you tell me how much wire and what size I would require for the armature, and also the size of the field coils? —J. S.

Answer:—This enquiry involves the complete design of a dynamo, which is a rather complicated matter to explain in this short space. The amount of wire required for the winding of a dynamo of the capacity you mention to work at 100 volts, as this depends on the speed, size of armature, nature of winding, whether lap or wave, series compound or shunt wind, number of poles, class of iron used in armature and poles. If your lamps were standard 40 watt lamps twenty of them would take 800 watts, and this at 100 volts would be 8 amperes. The capacity of the armature for current depends on the cross section of its conductors. This should be such as would allow about 2,000 amperes per square inch of conductor. A number 12 wire would do for this purpose as it has a carrying capacity of 10.2 amperes. The e.m.f varies directly as the square of the core and the number of turns on the armature.

To generate one volt it is necessary to cut 100,000,000 lines of force per second. Roughly allowing only 80 per cent of the number of turns to be effective, and assuming the class of iron used to have an intensity of 20,000 lines per square inch, would suggest making the armature seven inches diameter by 14 inches long. The wires laid in this would be in the form of a rectangle of 14 by 7 inches or 98 square inches, and this multiplied by 20,000 lines of force gives 1,960,000.

If we assume the speed to be 15 revs. per second, 900 per minute, this would give us 32,800,000 lines cut by one coil, but the coil having two sides would cut them twice every revolution. It would therefore only have to cut half the number of lines for 1 volt, therefore, 100,000,000 divided by 32,800,000 equals 3 turns for one volt or 300 turns for 100 volts plus 20 per cent. Assume you use four pole pieces and they are shunt wound, allowing 3 per cent for excitation current, you would need roughly about 1000 feet divided evenly over the four poles, number 24 wire.

All this is of course only approximate, but it shoud suffice, as we are not making a scientific design.—G. R. A.

BUILDS HIGHEST VOLTAGE SINGLE TRANSFORMER

Another achievement has been added to the long list of engineering feats of the engineers of the Westinghouse Electric & Manufacturing Company in the construction of the highest voltage single transformer ever built.

The transformer, which is 1,000 kv-a., capable of delivering 1,000,000 volts above ground was built for the Westinghouse Electric & Manufacturing Company's experimental laboratory at Trafford City, Pa. It is believed to be the only single transformer of such high above ground voltage ever successfully built and now in operation, having been installed recently at the Westinghouse laboratory.

The product has some novel winding features which make it exceptionally well suited for very high voltage work. It is of the core form construction which has always been used in the design of high voltage testing transformers.

The windings of this new transformer contain nearly 70 miles of wire and are assembled on the principle of a condenser bushing. It is divided into many cylindrical coils, each coil consisting of one layer of copper or turns wound on a micarta tube. As the coils increase in diameter, they shorten in length, precisely as does a condenser bushing, except that the tapering of the winding is the same at both ends. The turns of copper in the transformer take the place of the tinfoil in the condenser bushing.

The two sets of windings, one on each leg of the core, are cross-connected so as to produce a progressively increasing voltage above ground from the inner, or smallest, diameter coils to the larger diameter coils.

The windings of the large diameter or line coils consist of treated cloth covered cable so as to withstand surges that are produced when the apparatus being tested flashes over. A condenser bushing is used for bringing the line lead out through the cover of the tank.

The transformer is built on the principle of distributing electrostatic stress as developed by C. L. Fortescue, of the Westinghouse Electric Company, about eight years ago.

The terminal bushing is the largest ever built in the Westinghouse shops and on this account, special machines had to be fitted to turn the bushing. Its length is 19 feet and it is 41½ inches in diameter and weighs about 9,000 lbs. The static shield is 10 feet in diameter and 20 inches deep.

The construction of this high voltage testing transformer is the result of research work by Westinghouse engineers. The Westinghouse Company has made research a feature of its activities, believing that such work must necessarily precede commercial progress in any line. This has been particularly true in the matter of the gradual increase of transmission voltage. Testing facilities capable of producing voltages four or five times as great as the transmission voltages are necessary in connection with the development work on insulators and apparatus.

Some testing in the past has been done at voltages approximately 1,000,000 volts, but these tests were accomplished by connecting two transformers in series, grounding the connection between them and using the voltage between line terminals. One million volts was produced first in this way by the Westinghouse Electric & Manufacturing Company in 1913. When conducting tests by this method, an artifical ground is used

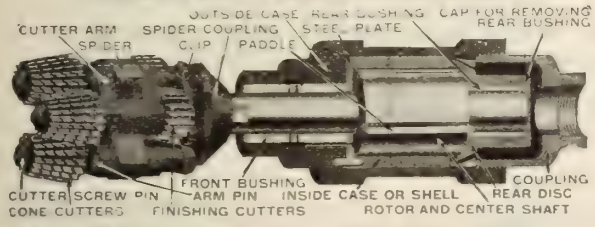
LAGONDA TUBE CLEANERS

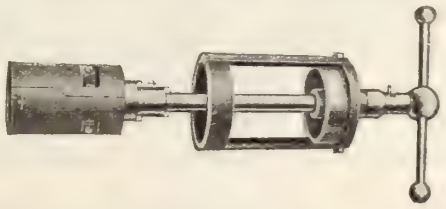


Sectional View, Lagonda Air or Steam Driven Cleaner

Lagonda Boiler Tube Cleaners are built right in every detail. They are fast, but thorough, long-lived, simple in construction. The above illustration shows a sectional view of the air or steam driven Cleaner.

Lagonda Cleaners are made to be driven by air, steam or water, and in all sizes for straight tubes or curved, in fire tube or water tube boilers. We will gladly send catalog and give full particulars.

LAGONDA TUBE CUTTERS



Lagonda Tube Cutter

Cutting boiler tubes is a simple operation when you are equipped with a Lagonda Tube Cutter. It makes a quick, clean cut, may be operated by one man and can be equipped with extension shaft for cutting tubes at any point. Descriptive bulletin and full information upon request.

B&W Marine and Land Types Steam Boilers

STOKERS AND FURNACES
SUPERHEATERS
BOILER MOUNTINGS AND ACCESSORIES
FEED WATER SOFTENERS AND FILTERS
FEED WATER PUMPS AND HEATERS
COAL AND ASH CONVEYORS
ELECTRIC CRANES
ETC., ETC.

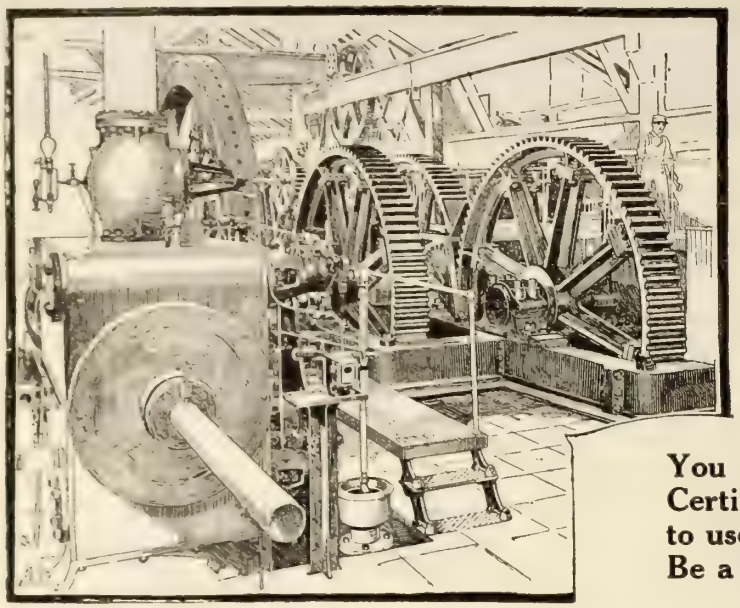
YOU Can be a CHIEF ENGINEER

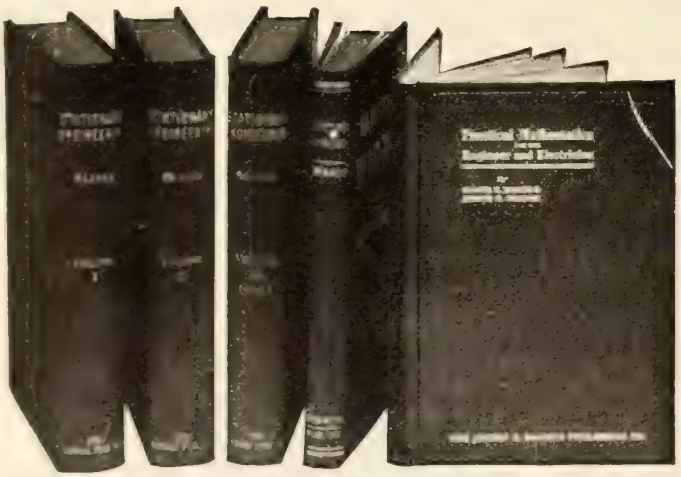


YOUR CERTIFICATE

You don't have to be told what this Certificate will mean to you—a chance to use your head instead of your body. Be a Trained Man!

Give us a chance to show you how to get this Certificate and be a CHIEF ENGINEER

COMPLETE COURSE IN STATIONARY ENGINEERING



covering every branch of power plant work, including Steam Engineering, Practical Mathematics, Electric Wiring and Mechanical Refrigeration. The Course has been prepared by a staff of experts working under the personal supervision of Joseph G. Branch, B. S. M. E., for many years Chief Engineer of the City of St. Louis and head of the Examining Board of Engineers for that City. Although complete in every detail, the Course is written so simply and clearly that **anyone can understand it.** No useless theory—but all the straight facts you need to pass the Engineer's Examinations and become a Chief Engineer.

You Get All These Books at Once FREE

Complete Instructions—36 Lessons

with Examination Questions on each Lesson
Just what you must know

Special Offer—Mail Coupon Quick

The price of the course is extremely low and just now we are making a **special limited offer** to those who reply to this advertisement. This remarkable offer reduces the cost of the complete course to a very low figure. You will be astonished to find how little this tremendously valuable training will cost you. Mail coupon at once for full particulars and special monthly terms.

FREE COUPON

Joseph G. Branch Institute of Engineering,
JB-4 Branch Building,
3917 Grand Blvd., Chicago.

Without obligation, please send me information how to get a Stationary Engineer's Certificate and full information about your course and Special Terms.

The new building planned by Ontario Hydro Electric Commission on University Avenue, Toronto, will cost approximately $500,000 and will involve about 450 tons of steel. It is understood that the Robert Redford Co. is considering the erection of an office building near Bay and Wellington Sts. This building erection is under contemplation but a definite decision is not expected for several weeks at least. The highways department of the Ontario Department of Public Works is proceeding with some bridge construction. A larger programme of bridge construction is understood to be under consideration.

The Midland Engine Works, manufacturers of steering engines and gasoline marine motors, are adding to their line a marine motor of the Scripps type. For the present, they will build them in four cylinder size, 25 to 40 horse power adaptable to cruiser types of boat from 35 to 40 feet or for speed boats 20 to 25 feet length. J. Bruce Hanly, the manager, who is an authority on motor and water boat construction, states that for a wide range of purposes this type of engine appears to him as one of the most uniform in his experience. In time he hopes to develop three sizes, two, four and six cylinder. His plans are to have 25 ready for the early summer demand.

Canada Electric Castings, Limited, are building on the site of the foundry of Canada Electro Foundries, destroyed by fire, a two story foundry 250 ft. by 50 ft., for which they are using the steel frame and other material bought from the Baldwins when they dismantled the Collingwood Steel foundry. W. H. R. Burrows, the manager, states that he hopes to have his new plant in operation by the middle of April. He is specializing in steel castings, including grinding balls, for the mining and concrete industries. His equipment will include 2 electric, three phase furnaces of the Heroult type, with Volta attachments, giving him a daily capacity of 18 tons.

Rebuilding of furnaces and extensive additions to the plant of Pilkington Bros. at Thorold, Ont., are responsible for a temporary close down of the plant, according to a statement issued by J. E. Harrison the Canadian general manager of the company. Coupled with that statement, Mr. Harrison declared that he was looking forward to a revival of the building trade that would control to an extent the speed with which the alterations would be accomplished.

Electrical energy is the power of the present and is likely to become more important year by year in the life of the Canadian people. A writer in Pulp and Paper magazine stated lately that the investment in electrical development of Canadian water powers is already $475,000,000 and will be not less than a billion dollars by the year 1940, if the present rate of growth in installation continues. The power now utilized represents coal that would cost $148,000,000 yearly. By 1940 it would be necessary to burn 42,000,000 tons of coal yearly at a cost of $336,000,000 to provide the power this writer estimates will be produced from Canadian waterfalls.

The British-American Fuel & Metals Ltd., McKinnon Bldg., Toronto, are representing in Canada, sixteen mines of the Pittsburg and Younghiogheny districts, also the West Penn. By-Products Co. The object of this company is to give a direct service between the mines and the consumer. In their fuel departments they have a production of bituminous coals of nearly 10,000 tons per day. The directors include some well known steel manufacturers and coal producers on this continent. The general manager, Major S. Snell, A.M.E.I.C., late Royal Engineers, states that the company has successfully sold fuel to consumers in Canada upon a technical basis, and that they are in a unique position to supply consumers with a fuel most suitable for their requirements and thus secure for them, the greatest economy and efficiency.

Yarrows Limited, Vancouver, B. C., has been awarded the contract for repairs to the Government steamer Givenchy which struck and was submerged for six weeks near Bella Bella, three months ago. The work will cost about $10,000.

Commenting on the possibility of a strike among the coal miners of the United States, H. A. Harrington of the Coal Exchange of Canada stated that a lengthy duration of suspended operations, would result in considerable inconvenience to users of American coal in Ontario. Canadian authorities will likely take steps to minimize coal shortage.

McColl Bros., 67 Bocelier St., Ottawa, will erect a warehouse and three storage tanks.

SOME BOILER QUESTIONS.

(Continued from page 37)

Question: — Would you recommend steam soot blowers, where steam is at 100 pounds pressure, or, would it not be better to use compressed air with these soot blowers?

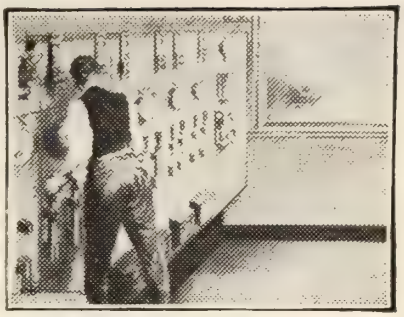
What do you consider the correct distance for grate of boiler for a return tubular boiler, 75 H. P.?

With a grate surface of 25 sq. ft., what evaporation should we expect? How much soft coal should this burn?

If we should lessen our grate surface, would it be practical to shorten the grate surface alone, rather than both narrowing and shortening grate surface?

Do you recommend graphite to be used in the boilers? If not, what do you recommend?

Answer:—It is preferable to use steam for soot blower purposes owing to its higher temperature and also because it is likely to be much more free from moisture than air. Further, you have a means of blowing whenever there is steam on the boiler without



Careers for Canadians in ELECTRICITY

As Canada, with its unrivalled water-courses, is now a wonderland of electric power, Canadian youths have a field of unlimited opportunity in which to win real success in life. In the near future there will be amazing electrical development throughout the Dominion and every boy and man who knows the why and the how of electricity—who has been trained to apply his knowledge with skill and understanding—can at all times be assured of a well-paid position and have within his reach one of the rich plums of the industrial world.

Boys! If you are ambitious, or if you would ensure against indifferent wages and perhaps frequent unemployment, you could hardly do better than take the necessary steps to become expert in some special branch of electrical work. Let us send you a Booklet of information about the famous method of the International Correspondence Schools, which is fully qualified to help the boy or man who really wishes to enjoy the advantages of a substantial career, in electricity or any other important line of work.

Just mark and mail the coupon. This doesn't obligate you in the least, but will bring you the finest story of opportunity—**your** opportunity — you ever read in your life.

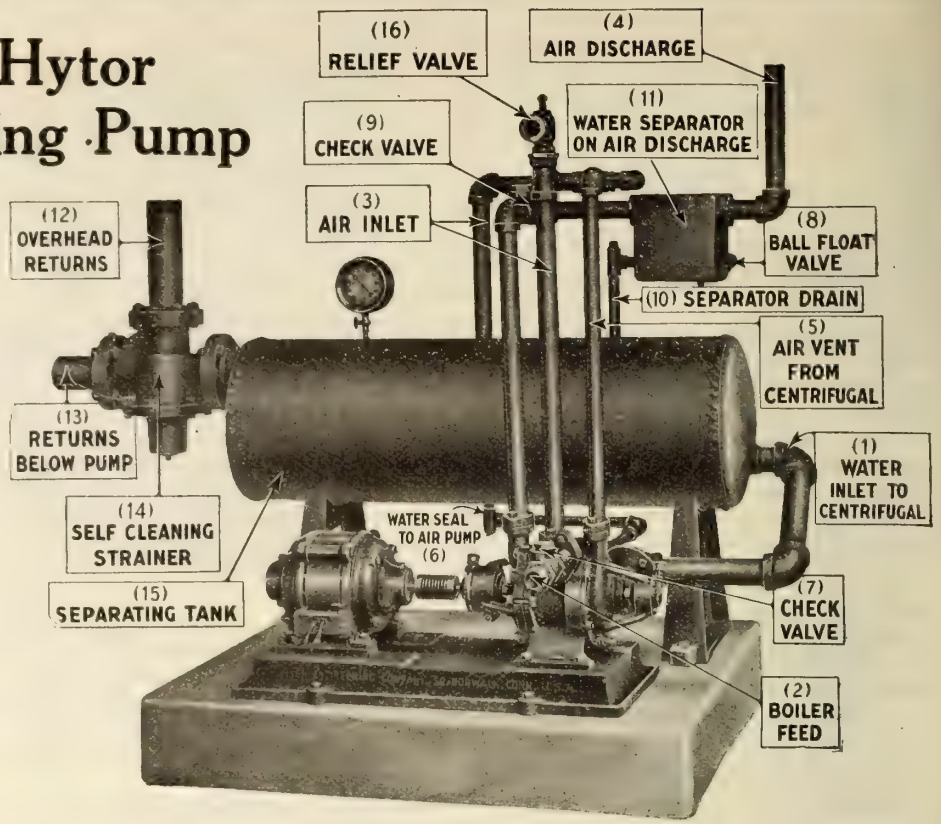
The Jennings Hytor Vacuum Heating Pump

THE ADVANTAGES of vacuum in connection with steam heating are well understood, but in installing equipment consideration should be given economy, efficiency and durability. In these respects the **Jennings Hytor Vacuum Heating Pump** deserves careful attention. It is distinctly in advance in principles of design compared with other types; principles of design which assure reliability, perfect service and low upkeep cost. Another feature is compactness, and the horsepower required for its operation is less than half that consumed by other vacuum heating pumps of similar capacity. **Study the illustration, then write for catalog.**



The Arthur S. Leitch Co., Ltd.

1001-2 Kent Building
TORONTO

having to start up an air compressor for this purpose.

A return tubular boiler of 75 horsepower should be set with the shell of boiler at least 38 inches above the grates and 42 inches would be a good height.

With a grate surface of 25 square feet and natural draught you should be able to burn 300 lbs coal per hour.

Your evaporation will depend on the temperature of feed water and the pressure of steam carried. Eight pounds of water per lb. of coal is an average performance.

It is quite practicable to shorten the grate only and this makes firing easier as well as cleaning. There is not much difficulty in getting at the side of the grate but there is at getting at the back of a long grate.

Graphite is useful under some circumstances and can be used with safety. Without knowing the conditions of the particular boiler referred to I would not make any recommendations

SULPHUR IN COKE

The general problem of decreasing the sulphur in metallurgical coke and devising desulphurization processes demands that some knowledge be had of just how the sulphur in coke occurs. Unfortunately this is not known and has led to several futile attempts to determine in what form the sulphur in coke occurs. A new method of attack has been outlined by the Bureau of Mines which promises to give much more information on this subject. This method makes use of the passage of hydrogen through the hot coke thereby giving a means for measuring the dissociation pressure of the carbon-sulphur combination. Application of the phase rule to these results will indicate whether the sulphur is present as a compound, a solid solution, or absorbed. The results so far obtained by the Bureau of Mines seem to indicate the presence of a compound but further work will be required to substantiate this and study its properties.

HEAT OF DISTILLATION.

An investigation regarding the heat of distillation of coal is being conducted at the Pittsburgh, Pa., experiment station of the Bureau of Mines. This investigation has for its object the determination of the amount of heat evolved or absorbed through chemical reaction during the process of destructive distillation of coal. Such information will be of value to the by-product coking and gas industries in that it will give them a more accurate knowledge of the thermal requirements of their ovens and retorts. The problem is being attacked by distilling small amounts of coal in a bomb calorimeter, the necessary energy being supplied electrically and being accurately measured by electrical means. The heat effect of the standardized amount of electrical energy required to distill the coal is measured in the calorimeter and compared with the effect of the same amount of energy supplied to the products of distillation in the calorimeter during a parallel experiment. The difference between the two effects gives the reaction heat of the coal, positive or negative as the case may be.

BUILDS HIGHEST VOLTAGE

(Continued from page 42)

which is one-half of the test voltage below ground. Results obtained by this method, however, are rather questionable, even when conducted with great care. Much more reliable tests can be made by means of a single transformer capable of delivering the full test value above ground. The necessity for such accurate test data resulted in the construction of the new testing transformer by the Westinghouse Company.

The Bureau of Mines has undertaken, at the Pittsburgh Experiment Station, an investigation of the mechanism of scale formation in steam boilers. The object of the investigation is to determine if the character of the precipitates forming in boilers may be made to assume a form in which they do not attach themselves to the walls, and also to ascertain if the material in the boiler wall exercises any influence. The work will be done in co-operation with a company manufacturing combustion appliances, which will bear all expenses.

Saves When You Use

Time is a big item of cost in testing gauges. With an Amercian Dead-Weight Gauge Tester you can test three or four gauges in the time ordinarily required to test one with most other instruments. This is partly because you can hold the pressure at any point as long as desired, thus making it quick and easy to take accurate comparisons of the gauge reading at any point on the dial with an

AMERICAN DEAD WEIGHT GAUGE TESTER

Another time-saving feature is in the fact that the American is the only completely self-contained tester on the market.

In addition to saving minutes and therefore saving money every time it is used, the American also saves money in the long run, for its rugged construction means long life. It is lighter, less bulky and therefore handier to carry around than most testers.

Made in various sizes for pressures from 5 lbs. up to 1000 lbs. Other equally effcient types for higher pressures.

Our interesting Gauge Tester Circular sent on request.

Get Behind the Premier!

THE amazing facts of Canada's immense loss of population within the past few decades—as revealed by the census—have given a rude shock to all thinking Canadians. To retain its newcomers as citizens and the sons of its citizens as builders of the Dominion, Canada must assure them at least a modicum of prosperity. In a forceful, trenchant, characteristic article, Agnes C. Laut discusses these issues in the

MacLean's Magazine for March 1st

"What we need," says Miss Laut, "is an united Canada—one unified puissant nation. Each little unit—the Maritime Provinces, Quebec, Ontario (the manufacturers' Paradise), the Prairie Provinces, British Columbia—has pulled for its own little ends, its own little local wants, forgetting that a nation—like a human body—can only attain perfect well-being when all the parts are in well-being, from its little toe (with apologies to P.E.I.) to its stomach (with my compliments to the grain-growing prairies). . . . .

"Mackenzie King won. My hat off to him and my sympathy with him; if I had twenty-five thousand miles of adhesive plaster in my possession I would send it to him, to help bind up in unity of aim, action and destiny the disruptive forces of class, creed, race, section, which he must unify if Canada is to avert financial catastrophe and forge ahead in his lifetime to a nation of forty to fifty million people, as it ought."

A Peaceful Session? Perhaps!

By J. K. Munro

The tariff is dead and will stay dead—until the next election; the railway issue is dormant but will show unmistakable signs of life. So says "J. K.," in a timely political article in which he discusses whether the members of the new Cabinet will make the House a talker's Paradise or a worker's sanctum.

Other Striking Fact and Fiction Features:

RANCHING ON THE BOTTOM OF A LAKE—by Charles C. Jenkins. The romantic story of the Kleskun Ranch, which a few years ago was several feet under water, and now—!

TAKING DOWN OUR MEMBERS—by T. M. Fraser. Some of the humorous side lights as viewed by the Hansard reporters in the House of Commons, during the past half century.

WETHERELL'S ROMANCE—By Sullivan.—A poignant piece of short fiction, by a master writer, describing what happened when a consumptive tried to sell mining claims in London, England.

TOTEM POLES.—By Charles P. Cushing. A story of British Columbia and Alaska, of a man who found romance in business—and how he wavered between two girls.

MOSTLY SALLY.—By P. G. Wodehouse. The conclusion of this entertaining serial, in which Sally meets her just reward. And Ginger gets—well—.

PRICED ABOVE RUBIES.—By Luella Stewart . One of those graphic little bits of a cross-section of real life, delineating a story as old as the hills, but ever absorbing.

THE MAUVE MICRASTER.—By G. Appleby Terrill. The account of what happened when a Professor, who collected queer stones, and a girl, who had a queer brother, fell in love with each other.

THE MARCH HARE.—By Guy Morton. A business romance, on facts which recently occurred in a prominent Canadian industry; this handsome young business man not only makes very satisfactory profits by turning the tables on his rivals, but manages to secure a beautiful girl as a prize.

BACK TO THE DAYS OF COTTAGE CRAFT.—By Gertrude E. S. Pringle. Miss Helen Mowat started her industry with $10 capital—and more than a moderate amount of brains. But—she had an idea—and last year she paid out $12,000 to her workers.

Review of Reviews.—This department alone is worth far more than the price of the magazine. It gives a review of world-wide matters of current interest, condensed in most readable form.

Canadian Fairbanks-Morse Company, Limited

St. John, Montreal, Quebec, Ottawa, Toronto, Hamilton, Winnipeg, Saskatoon, Calgary, Vancouver, Victoria.

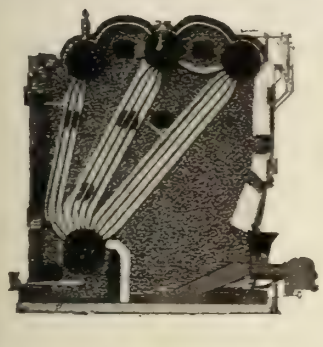

Illustration at left shows the use of Plastic Fire Brick in a modern high stoker - fired furnace, including side and front walls, door arches, bridge wall and baffles.

One-Piece Boiler Furnace Linings

Complete linings including door arches, side walls, and bridge walls are easily built in any type of boiler by any intelligent workman without special forms, shapes or previous experience. A pair of willing hands, a mallet and trowel being the only tools necessary. The use of Betson linings and baffles increases efficiency of boilers, reduces repair costs and saves the fireman a lot of hard work.

BETSON'S REG. U.S. PAT. OFF. TRADE MARK CANADA

PLASTIC FIRE BRICK

is not a coating or surface finish, but a plastic material from which solid one-piece fire brick wall linings are constructed. It is a compound of fire clays of highest refractory properties and capable of withstanding the stress, strain and wear to which boiler linings are subjected.

Betson's is backed by over twenty years of satisfactory service. Do not experiment with substitutes or imitations.

We have prepared a booklet with much valuable information for the man interested in the care of boilers. A copy is yours for the asking.

MONCRIEFF'S GLASSES

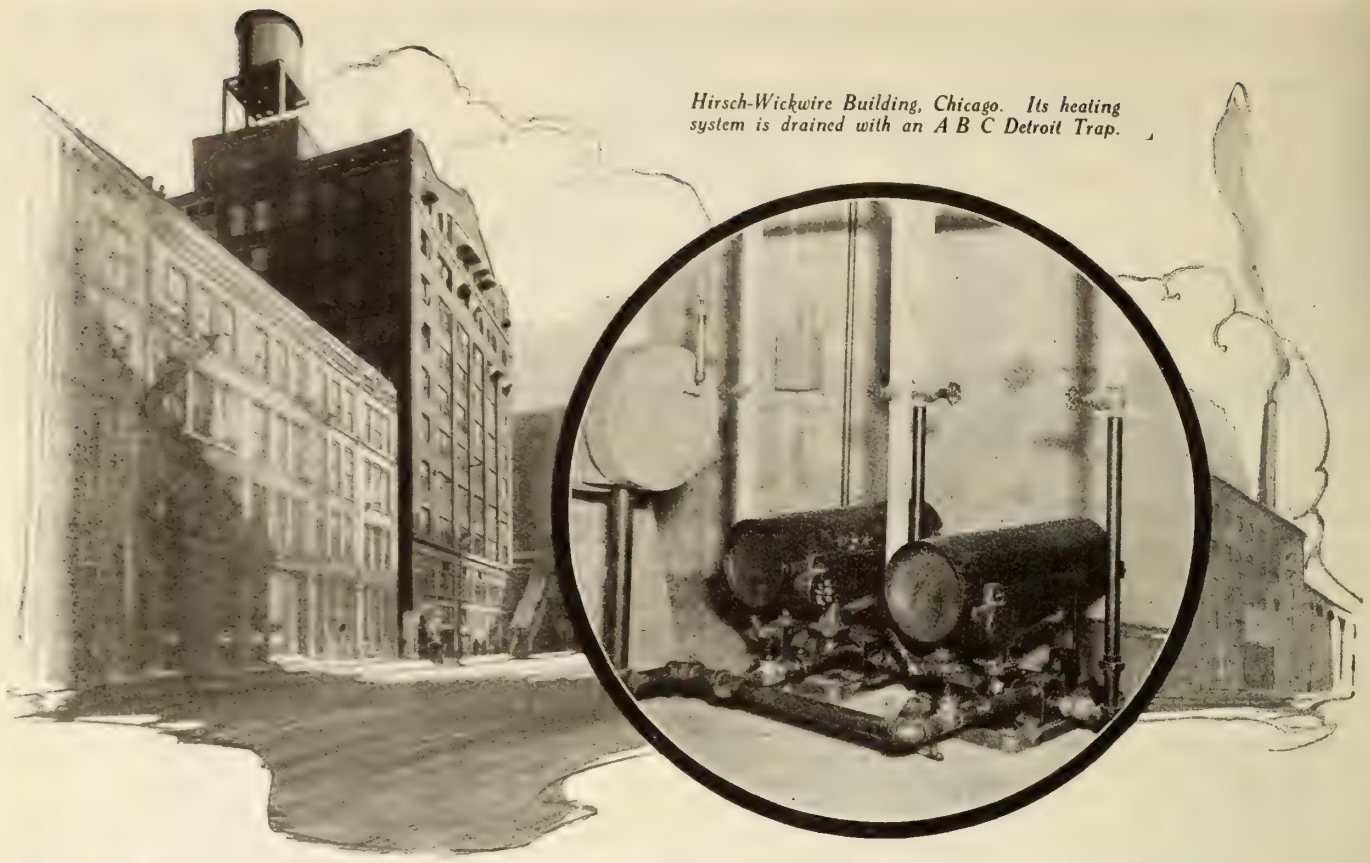
"UNIFIC" WATER GAUGE

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

Canadian Representative: W. J. WALL, 134-136 Bleury St., MONTREAL, CANADA



Hirsch-Wickwire Building, Chicago. Its heating system is drained with an A B C Detroit Trap.

Keep Your Steam Heated Equipment at High Temperature—Return Your Condensation Direct to Boilers and Eliminate Pumps—Save 15 per cent. of Coal

Steam drainage equipment if properly installed, will keep your steam-heated machinery and apparatus at high temperature and speed up production.

Efficient steam drainage is made certain with the A B C Detroit Trap System which returns the condensation at high temperature direct to your boilers.

By returning the condensation to boilers, without the aid of pumps, a fuel saving is effected because it is not necessary to allow the condensation to cool to 212 degrees—the highest temperature at which the condensation can be handled by pump.

If you are operating a plant with steam power—if you have a steam drainage problem—bring it to the attention of our engineers. Let us demonstrate that with the A B C Detroit System you will not only increase your production but you will also lower your fuel cost at least 10 per cent. Write for our booklet completely describing the A B C Detroit System.

"PALMETTO" PACKING

REG U S PAT OFFICE

Has No Rubber In It

because rubber quickly vulcanizes under the extreme heat of present day pressures, and not only fails to give the intended resilience, but is harmful to the packing itself.

Many years ago when steam pressures were so low as to carry practically no great amount of heat, rubber in packing served a useful purpose. But it has no place in packings for present day high pressures, especially where superheated steam and compressed air is used—**then why use a packing containing rubber?**

Which do you prefer in your packing—rubber or lubricant? You cannot have both, as oil kills the rubber.

"PALMETTO" is the most thoroughly lubricated packing made.

Let us send you working samples - no charge.

The Straight Course

to freedom from boiler setting troubles is by way of

PLIBRICO JOINTLESS

FURNACE LINING

How do we know?

Because hundreds of PLIBRICO users tell of the satisfaction PLIBRICO has given them with its smooth, jointless, heat-resisting walls. They tell of fuel saved, of time saved, of money saved. They tell of absence of shutdowns, and of the readiness for peak loads of the boiler equipped with complete PLIBRICO settings.

L-48 on "Modern Furnace Building" tells about the "PLIBRICO way."

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

DISTRIBUTORS:—Beveridge Supply Co., Ltd., Montreal, Que.; Shell Bar Boico Supply Co., Ltd., Toronto, Ont.; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply & Fuel Co., Winnipeg, Man.; Gorman's Ltd., Calgary, Alta.

JOINTLESS FIRE BRICK CO.

1142 Clay St., Chicago, Ill.

One of these Cold Days, try this simple Candle Test on your Boiler Settings

No leaking out of hot gases or pumping in of cold air with **Plibrico** jointless furnace linings. Turns every ounce of coal into live steam—increases boiler efficiency and reduces fuel consumption.

Satisfactory and convenient.

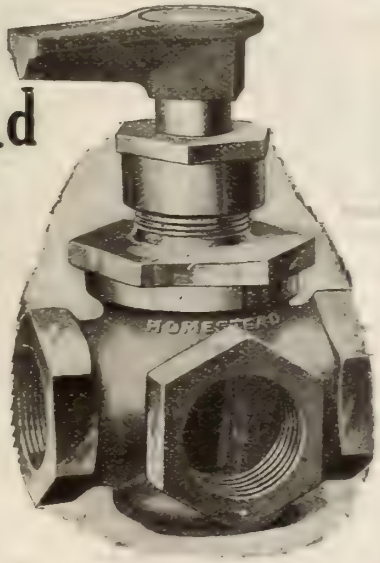
Can also supply you with a material for sealing up exterior settings.

BEVERIDGE SUPPLY CO., LTD

628-630 St. Paul St., West

MONTREAL

Homestead Quarter-Turn Valves *For Quick Opening and Quick Closing*



Three-Way Valve

You want a quick-opening valve, you want a quick-closing valve—then you should adopt Homestead Quarter Turn Valves. They are in addition always tight-closing, and provide an "unobstructed" flow. Homestead Valves are furnished in straightway, three-way, four-way and angle patterns. They are equally adapted for steam, water, air, gas, heavy, gritty fluids and any other power or industrial plant service. Used in thousands of plants in place of globe and gate valves. Order a few to-day.

HOMESTEAD VALVE MFG. CO.

HOMESTEAD, PA.

New York Office : 247 Lafayette St.

Stop Wasting Oil

The De Laval Oil Purifier returns to service lubricating oil or transformer oil which would otherwise be thrown out. Better still, its continued use constantly maintains the efficiency of such oils.

The De Laval does its work instantaneously, thoroughly and economically by centrifugal force. It is the modern method of making turbines and Diesels give longer and better service, and of prolonging the life of the oil used to lubricate them. It is the far more economical method of maintaining the dielectric strength of transformer oil.

No matter which of these tasks you give a De Laval—you can use the same machine for both — you have absolute assurance that the work is being done better and more economically.

Why Struggle Under a Load of "Wasted Power" and "High Overhead"?

If overhead costs are piling up, look to your belts. Cheap, inferior quality belts can mean only one thing—wasted power. Wherever belt slippage and frequent interruptions occur, power waste can be counted on.

Eliminate this unnecessary expense by adopting D. K. McLAREN'S **Genuine British Oak Turned** LEATHER BELTING—the long service belting that spells economy.

D. K. McLaren's belting gives long power-saving service because it is quality built. Consequently it is the most economical.

Every user is guaranteed of never-varying quality—because every belt is made from the world's best leather. Only the back portions of the choicest hides are used—tanned by the famous British Oak Tanning process.

Our nearest branch will supply full information.

Jenkins Valves

In the Berliner Gramophone Plant

THE BERLINER GRAMOPHONE COMPANY'S PLANT. ST. HENRI. MONTREAL.

Much of the efficiency of large industrial plants such as the Berliner Gramophone Company is dependent upon dependable valve installations.

It is not surprising therefore to find Jenkins Valves playing an important part in the daily output of "His Master's Voice" products from the big modern plant pictured above.

Jenkins Valves are guaranteed good by the quality of the metal used in their manufacture and by the practical valve making experience of some 57 years which is built into every size and type.

You'll know they're Jenkins by the name within a Diamond Mark cast on the body.
At supply houses everywhere.

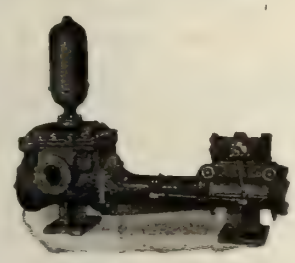
The way in which the people of Hama get their drinking water.

The Syrian City of Hama is known for its large and ancient waterwheels, which supply the city and fields above with water. The wheel illustrated here is one of the largest of its kind in the world. It has a diameter of 70 feet, and is constructed of fine mahogany wood.



Boiler Feed Pump

Only the best of materials are used in the manufacture of American-Marsh Pumps—materials that have been called upon to demonstrate their merit before they could enter into American-Marsh construction.

KERR

("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributors of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

The Vital Question
How much Heat is in the Steam you pay for?
Fuel is the largest single item of expense in power plant operation. Do you know that the money it costs you purchases heat and not just so many tons?
For the same weight of fuel you buy and burn, you receive more heat when you superheat your steam. It is the additional heat in superheated steam which enables your engines and turbines to operate more economically.
The heat is in the fuel, and the higher you superheat your steam, within practical limits, the less fuel you have to buy.
That is why ELESCO Superheaters pay such high returns. They save fuel. This advantage and other reasons why it pays to superheat are fully explained in our Bulletin NT-7. Send for it now—now when you are thinking of ways and means to reduce your production costs.

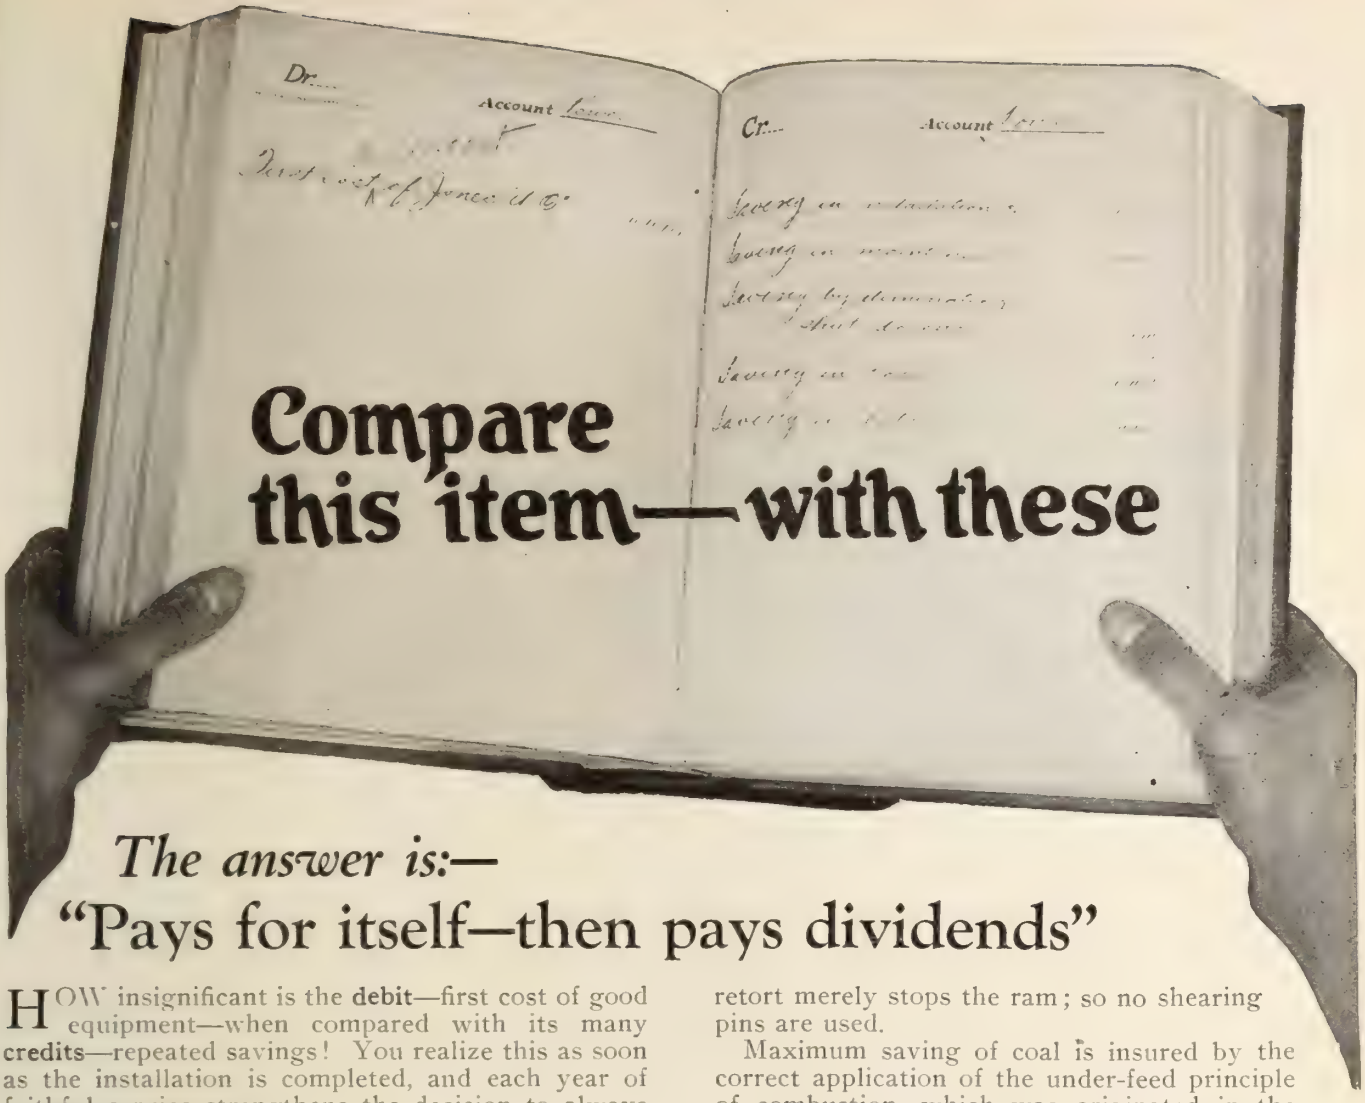
ALL INDUSTRIAL USES

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.



Compare this item—with these

The answer is:—
"Pays for itself—then pays dividends"

HOW insignificant is the **debit**—first cost of good equipment—when compared with its many **credits**—repeated savings! You realize this as soon as the installation is completed, and each year of faithful service strengthens the decision to always install the best equipment that money will buy, regardless of first cost.

Which stoker will save most? Weigh that question carefully, and you will decide that it is the stoker which fulfills all requirements, yet is simple enough to operate without shutdowns and with lowest maintenance cost.

Consider the Jones "A-C" under the headings that would appear on the credit side of a "power account"—

At the outset there is a saving in installing the Jones "A-C," because there are no shafts to line up and because no expensive special brick or concrete work is necessary. Maintenance cost is extremely low, because of the rugged simplicity of the stoker. There is only one simple moving unit—no moving parts in the fire.

Shutdowns of any consequence are impossible because of the rugged simplicity. Foreign matter reaching the retort merely stops the ram; so no shearing pins are used.

Maximum saving of coal is insured by the correct application of the under-feed principle of combustion, which was originated in the Jones Stoker—by the widely praised ability to burn all grades of bituminous coal without clinker troubles—by the automatic regulation of fuel and air supplies—and by the individual control of retorts, to mention only a few outstanding reasons for correct combustion. The self-cleaning feature and automatic operation greatly reduce labor costs.

But notwithstanding these unapproached economies, the Jones "A-C" costs no more than other multiple retort stokers intended for the same range of duty. Do you wonder that it pays greatest dividends?

Look into the items that determine stoker value with the assistance of the interesting book, "Ten Points of Jones Superiority."

JONES Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co. of America are made available for Canadian power users. Thus this strictly Canadian Stoker is backed by world-wide experience and unequalled engineering ability.

Pressure Reducing Valves

Dependable Pressure Regulation

MAINTAINING correct reduced pressure on steam, air and gas lines is too important to be entrusted to valves of untried reputation.

More than 50 years of engineering experience is back of the Morrison Reducing Valve design.

Morrison Reducing Valves are furnished in all sizes with bronze or iron bodies for all ranges of pressure up to 300 lbs.

"Every Installation is a Demonstration of Merit."

Files Hand Stokers Getting Results

PANTHER RUBBER COMPANY, LIMITED

GENERAL OFFICES AND FACTORIES
SHERBROOKE, QUE.

Ans'd Sept. 26/21.

SHERBROOKE, CANADA September 23, 1921.

The Waterous Engine Works Co. Ltd.,
Brantford, Ont.

Gentlemen:

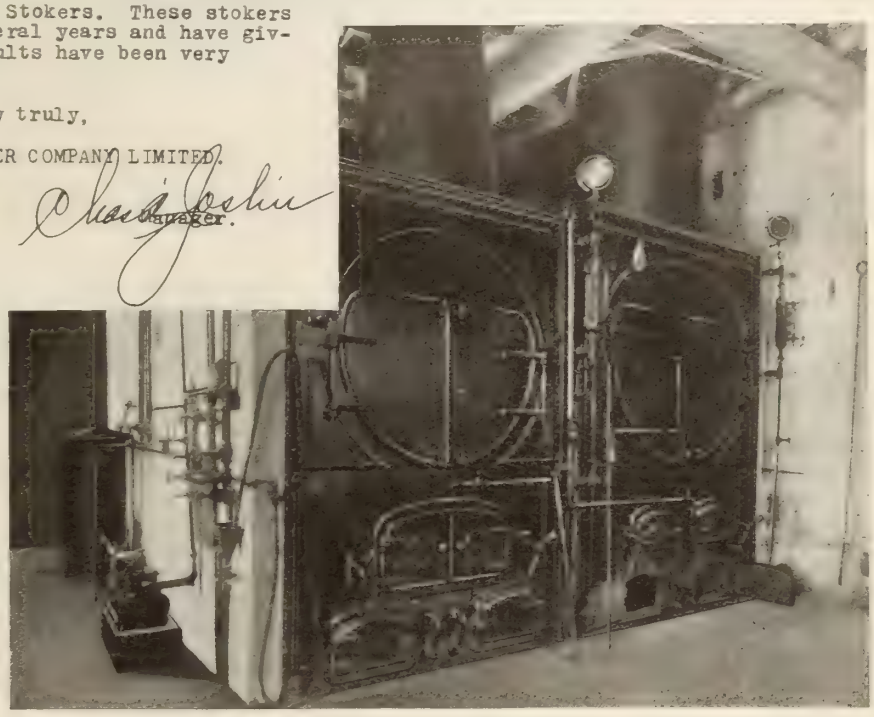
In reply to your letter of the 8th instant we have in our plant the Files Stokers. These stokers have been in operation for several years and have given excellent service. The results have been very satisfactory.

Yours very truly,

PANTHER RUBBER COMPANY LIMITED.

Chas. A. Joslin
Manager.

CAJ/RMK



It is the uniform excellent service and general satisfaction that have caused progressive men to select **Files Stokers.** These are typical of the more complete data we have compiled:

One installation (3,600 H.P.) saved enough coal to pay for their stoker investment in five months.

A Files installation operated for five months continuously at an average rating of 223%—doubling their steam output.

Files stokers increased efficiency of one plant sufficiently high to warrant discontinuance of two out of eight boilers.

Here is a ready explanation of these achievements:—

1. **Complete volatilization of green coal, causing intensified combustion and smoke dissemination.**
2. **Correct distribution and proper proportion of air according to load carried**
3. **Fuel bed continuously kept clean, uniform and rich.**

Given the opportunity we will be glad to present these facts for your complete satisfaction.

LUNKENHEIMER
"Duro" Blow-off Valves

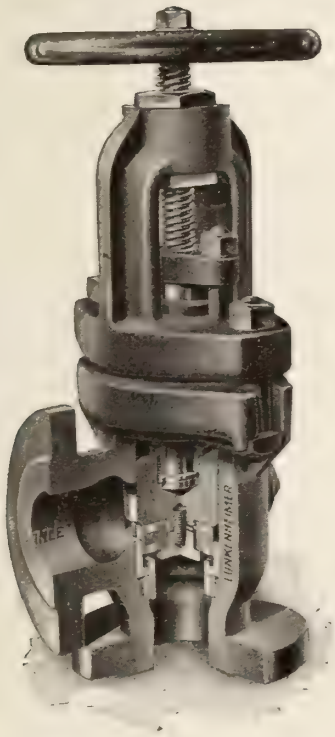

Fig. 897, Flange Ends.
Fig. 896, Screw Ends.

"Duro" Blow-off Valves prevent heat waste in blow-off lines. They remain tight under extreme operating conditions because they are not only made of wear resisting materials, but their design is such that the usual causes of leakage are eliminated.

The piston shaped disc secures a gradual release of the water due to its travel in the cylinder above the seat before full open position is reached. And when closing, the seating surfaces are automatically cleansed by the fine stream of water forced past the disc as it travels through the cylinder casing before seating. This action also minimizes wire drawing of the seat.

"Duro" Blow-off Valves contribute to efficiency and economy in plant operation and meet every blow-off requirement. Sizes 1¼ to 3 inches, in Iron Body Bronze Mounted Pattern for pressures up to 250 pounds.

Specify "DURO" BLOW-OFF VALVES and insist on their installation.

For

Self-Promotion And Sales Promotion

Are you interested in any of these fields—power—metal working—marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric, Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)

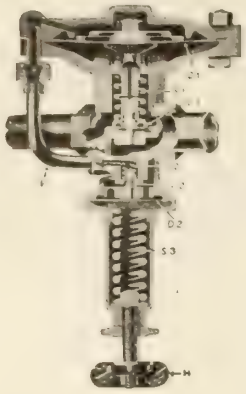
TRADE MARK REGISTERED



You Are The Loser

Unguarded steam disappears. It has no value. Once gone, it is gone forever.

AND YOU ARE THE LOSER

Fisher
Pressure Regulator
(Series 90)

will watch your steam. It will release exactly the desired amount of reduced pressure—and no more.

It is especially valuable in curing, drying, bleaching, dyeing, vulcanizing, evaporating and any other process dependent upon a uniform temperature or pressure.

It shuts off absolutely all supply of steam when the process it is serving is suspended. Actual service in thousands of plants throughout Canada has proven Fisher Power Plant Specialties to be long-lasting and accurate in the most trying and delicate operations.

Ask your dealer or jobber for full information about the Fisher line. Or write for "POWER PLANT SPECIALTIES." It is full of valuable information.

Jones "A-C" Stokers used in connection with hydro-electric development. The same stoker that is giving excellent results in large plants is also ideal for small plants. The saving is even more gratifying.

The Canadian Stoker

Jones Stokers are made in Canada by Canadians and are sold for Canadian money at par. Through special arrangement the extensive engineering resources of the Under-Feed Stoker Co., of America are made available for Canadian power users. Thus, this strictly Canadian stoker is backed by world-wide experience and unequalled engineering ability.

Since Hand Firing Won't Do Install a Real High-Duty Stoker

Too many stokers are merely substitutes for hand firing. By eliminating the waste of hand firing they effect economy—but not as great economy as is possible through **real** high-duty stoker firing. Small plants as well as large plants, to-day regard a stoker as a means of **economy** instead of an expense. First cost is considered only in relation to the dividend it yields.

The Jones "A-C" has proved its ability as a dividend producer by perfectly fulfilling the rigid requirements of high-duty stoking.

Its extreme simplicity—only one moving part, none in the fire—reduces maintenance and practically eliminates shut-downs.

The under-feed principle of combustion—a principle originated in Jones Stoker—provides maximum combustion efficiency, ability to burn poor grades of coal, and heavy overload capacity.

The automatic-cleaning feature and special tuyere construction overcome objectionable formation of clinkers on front, side and bridge walls. Automatic control of fuel and air insures even steam pressure under widely varying load demands.

What single investment will yield as great return as high-duty stoker firing?

The new Jones "A-C" Catalog explains this new coal and labor saver in detail. Ask for a copy.

Get Rid of Seepage with a Penberthy Automatic Cellar Drainer

TRADE PENBERTHY MARK

All Working Parts Above Water

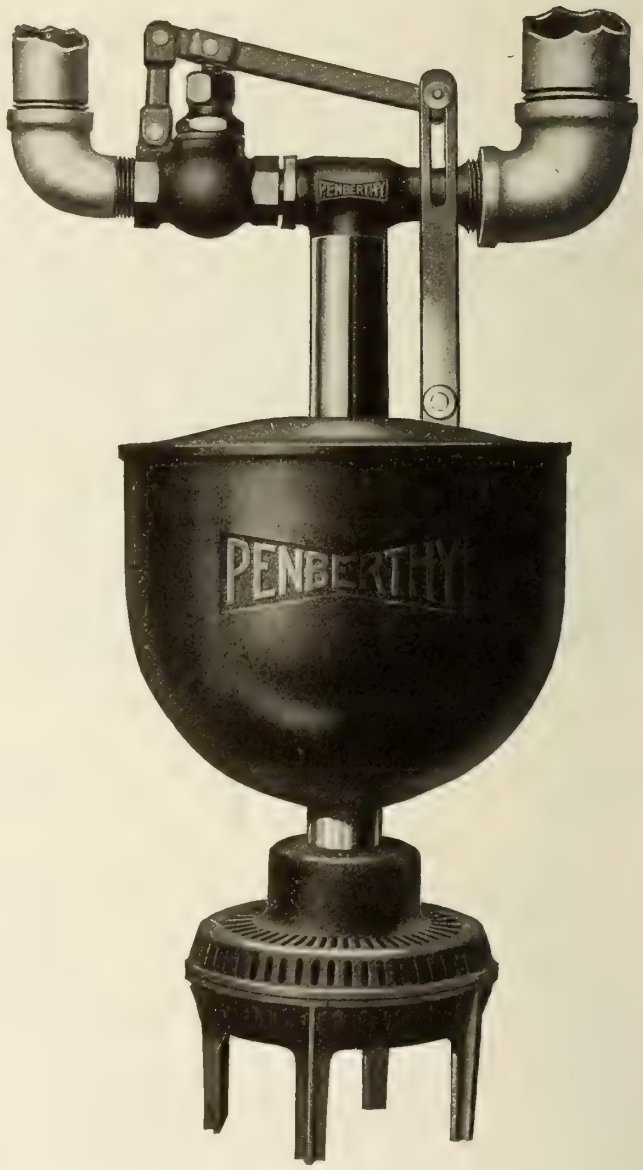
Cheaper and much more economical to operate than a pump, it automatically keeps cellars, store basements, scale pits, elevator pits, fly-wheel pits and building excavations dry and free from water.

Made in various sizes—from the household size up to the largest for draining building excavations.

Very strong and durable in construction—lasts for years.

All working parts are above water—not damaged by rust and very accessible.

Send for complete descriptive literature.



Penberthy Injector Co., Ltd.

Windsor, Ontario

Manufacturers of

Injectors, Ejectors, Oilers, Valves—Regrinding, Compodisc, Radio-Lubricators, Water Gages, Gage Cocks, Air Cocks, Grease Cups, Washing Machine Drainers, Water Heaters, Whistles.

THE MACLEAN UNDERFEED STOKER

Prevents Power Interruptions

Burning all classes of bituminous coal efficiently and maintaining a constant uniform steam pressure is the way MACLEAN UNDERFEED STOKERS take care of your steam requirements day in and day out, regardless of varying loads on the boilers.

The MACLEAN STOKER adjusts the coal feed and air supply automatically responding to sudden demands for steam without attention from the fireman.

It is easy to install—easy to operate; small cost of upkeep; no moving parts in the fire. Along with these and other advantages the MACLEAN STOKER makes savings that will soon pay for its installation.

May we estimate the saving to be made in your plant? You are under no obligation to purchase.

The Main Plant of the Montreal Street Railway

This Central Station, Containing Twenty-Two Water Tube Boilers, Turbo Generators, Direct Connected Reciprocating Units of Large Size, and All the Auxiliaries That Pertain to These Units, is a Sight Worth While

By T. H. FENNER

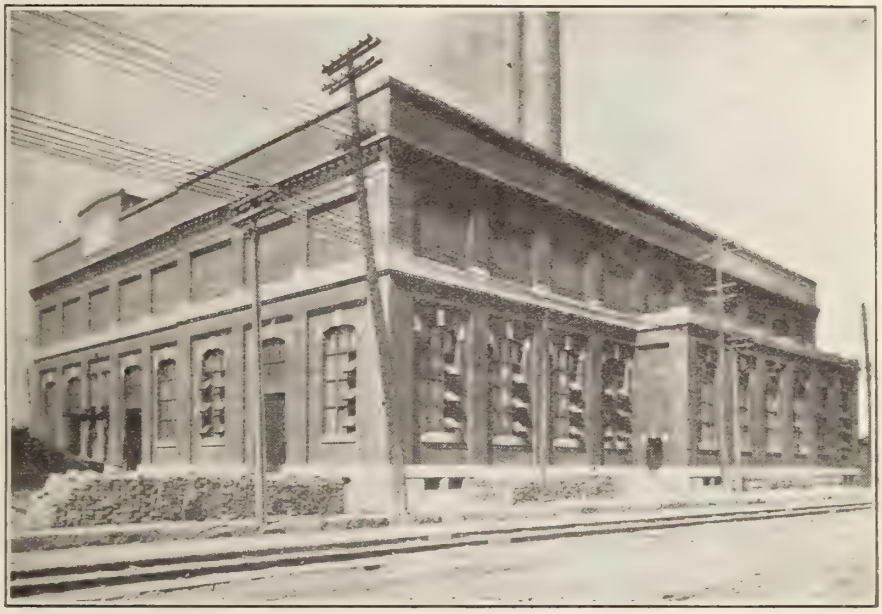
WHILE we are accustomed to hearing of central electric power and lighting stations of high powers driven by steam, they are usually situated in the United States, and one gets in the habit of associating all these big developments with that country. We do not have to go out of Canada, to find some examples of these large developments, and one of the best examples, and probably the largest, is the central plant of the Montreal Street Railway, at Hochelaga.

The station supplies the current for the whole tramway system of the huge city, delivering direct to the trolley wires from some of its units, and feeding out over high tension cables to the sub stations placed around the city at different points, with others. The station, while contained in one building, represents two different styles of practice in developing electric power, and is the more interesting for that reason. One end of the building is devoted to d. c. generation, while the other is sacred to the a. c. method. One sees the huge vertical cross compound direct connected engines of comparatively slow speed, in juxtaposition to the compact high speed and high powered turbines, and the relation between power and speed is forcibly impressed on one. This is particularly the case when looking down from the top platform of the three thousand k. w. McIntosh Seymour engine, which towers up at an impressive distance from the floor, at the 2,000 k. w. Bellis & Morcom turbo generator, which looks very tiny in comparison to its big neighbor.

The outside view of the building gives some idea of its general dimensions, although it fails to convey any impression of the depth to, which it goes underground. The illustration of the boiler, taken from the sub-basement shows the full height of the station to good advantage.

The General Arrangement

The building is divided into three floors, and is also divided longitudinally by a wall running down the centre of the building. The main floor on the south side of the wall is devoted to the turbo generators, steam engines, rotary converter, and the switchboard and offices. On the north side of the dividing wall on the ground floor, or main floor are the boilers. The engine room basement contains at the west end the pumping arrangements for the barometric condensers of the vertical engines and the workshop is also situated here. At the east end of the power house in basement and sub-basement are the circulating pumps, condensers, feed pumps, and heaters in connection with the a. c. side of the plant.



The Hochelaga Power House of the Montreal Street Railway

The basement in the boiler room is devoted to the ash-handling and coal-conveying arrangements, which include coal crushers at each end of the boiler room. The boiler room itself is divided into what is known as the high and low pressure side, the high pressure side supplying the alternating current generators and their auxiliaries, while the low pressure side is devoted to the d. c. current generators.

The foregoing having served the purpose of giving the reader a general idea of the arrangement of the plant, we can now consider the various units in greater detail.

The Boiler Installation

The boiler installation in total consists of twenty-two Babcock & Wilcox water tube boilers, both the cross drum and longitudinal drum type being used. The low pressure side, as the boiler installation supplying the reciprocating engines is called, consists of fourteen 550 rated h. p. two drum boilers, working at 150 lbs. pressure per square inch, with 70 deg. superheat, and fitted with Green economisers. These economisers are situated above the boilers in this case instead of the familiar method of placing them behind the boilers. This of course was due to consideration of space, and does not affect the efficiency in any way, the length of flue from boiler to economiser being about the same, or but little longer than in the ordinary arrangement.

Each boiler is fitted with the Babcock & Wilcox chain grate, and the coal is supplied to the hoppers through a Jeffries traveling automatic weigher. The conveyors we will come to later. Each boiler is fitted with an injector as well as the pump feed, in case of emergency. The feed arrangement consists of two Cochrane heaters delivering to Fairbanks duplex feed pumps in inches diameter by 18 inches stroke.

The economiser installation for this battery is divided into four economisers, each having a heating surface of 7,650 square feet. These economisers have the tubes arranged in sections ten tubes wide, there being sixty sections in each economiser. The tubes are nine feet long, and 4-9 16ths inches outside diameter.

The average increase in temperature of the feed water passing through the economisers is 80 degrees, and this results in an increase of about 7 per cent. in the overall efficiency of the boilers and furnaces. The increase in capacity of the boilers due to the use of the economisers is also 7 per cent. The power required to operate the economiser is only about 10 horse power, so that it can be readily seen that here is a case where the investment is well worth while. With an average flow through the economisers of 70,000 lbs. per hour and an average increase in temperature of 80 deg., there is a saving of 5,600,000 B. t. u. per hour. If the coal has a heat value as fired of 10,000 B. t. u. per lb. there is a direct saving of 560 lbs. per hour, or if a boiler horse power is taken at 34,500 B. t. u. there is the heat equivalent of about 160 horse power.

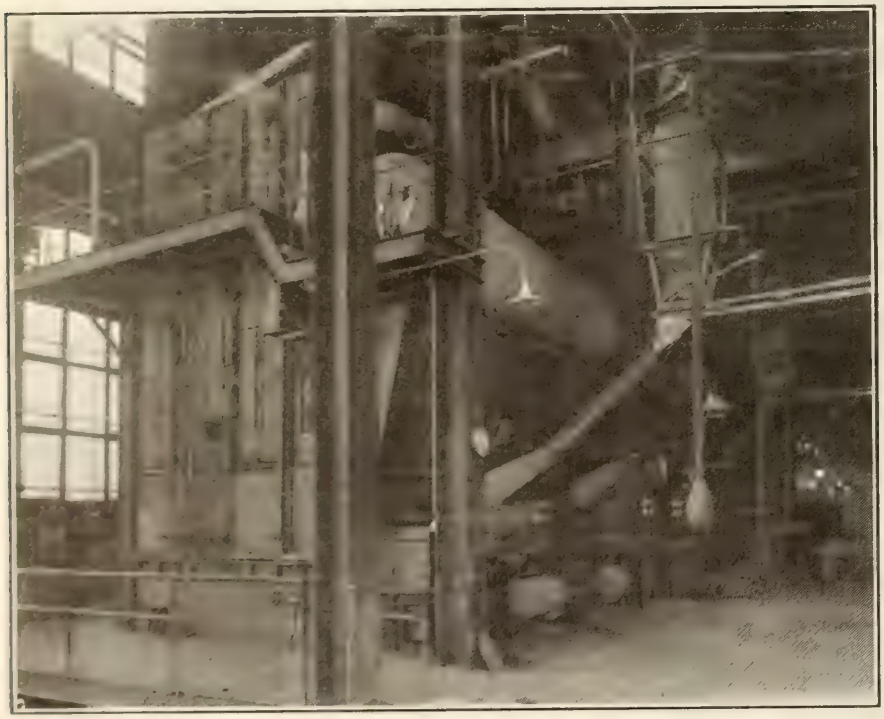
These figures are of course only approximations, but they show in some measure what influence the economiser has in the operation of a steam plant of average size. There is also the point to consider that these economisers constitute a large reservoir of heat, which is available for sudden emergencies such as are liable to arise in the operation of a street railway system.

View in boiler room showing chain grate stokers and coal chutes.

The stack for this battery is 235 feet high with a diameter of 12 feet, and the normal draught at its base is 1 inch water gauge. There is also an installation of induced draught fans for use when required.

Passing from the low pressure boilers, which are of course only low pressure in comparison with the others, we come to a battery of four 550 horse power boilers working at 200 lbs. per square inch, supplying steam for the a. c. turbo generator sets. These boilers work at a superheat of 190 deg., and are fitted with superimposed economisers with steel tubes.

There are still further four cross drum marine type boilers of 1,100 h. p. each working at the same pressure and temperature and these eight boilers constitute the high pressure side of the installation. All these boilers are fitted with precision draft gauges of the differential type, and also General Electric flow meters. There is a "Sarco" CO_2 recorder in the engine room connected with the flue gases from these boilers. The stacks for these boilers are of the Evase type, which operate on the ejector principle of inducing draught. There is a complete installation of Diamond Soot Blowers on boiler and economiser.



View of one of the 1,100 H.P. Boilers with superimposed economiser, and automatic travelling weigher in front

The Conveying Arrangements

The coal is brought into the yard, and there is a general storage capacity of about 30,000 tons available here. The coal is brought into the yards by cart, and is distributed and reclaimed by means of portable elevators. When ready for use it is dumped into hoppers at each end of the boiler room, and delivered by a chute into the coal crushers. The coal crusher at the low pressure end, or the west end of the boiler room, is a Babcock & Wilcox double roll crusher, capable of handling 45 tons of coal per hour. This crusher breaks the coal up into lumps about ¾ inch square, which is a suitable size for the chain grates. From the crusher the coal is taken away by a bucket conveyor, which travels through the basement practically the whole length of the low pressure battery, then goes up to the overhead bunker which has a capacity of 1,600 tons, travels the whole length of this bunker and then down again to the coal crusher. There are of course spilling arrangements for the buckets in the conveyor

A view showing the arrangement of the ash hoppers under the boilers, with the truck standing under the hopper. The small riddling hopper can be seen at the left of the truck

path in the bunker, so that an even distribution can be made. The coal from the bunker runs by gravity into the traveling weigher, and thence is directed into the hopper of any particular boiler where it may be required.

For the high pressure end of the installation there is similar arrangement, the bunker capacity at this end being 1,000 tons, the coal crusher being situat-at the east end of the boiler room in this case.

Thus far the coal conveying arrangement. After the coal has performed its function in the furnace the residue has to be got rid of, and we must go down the basement below the firing floor to see the arrangements for doing this.

The ashes from the end of the chain grate are delivered into a chute on the end of which there is a hopper, situated in the space under the boiler ashpit. There is one of these chutes and hoppers directly under each grate, and there is also another chute connected with the ashpit, and known as the riddling hopper. This is for handling the droppings from the chain grate which contains a certain percentage of unburnt carbon. This is of course kept separate from the main ash chute.

Along the basement floor runs a trolley rack which passes in front of all the chutes, and runs to the far end of the boiler room, or rather we should say the east end. Here there is a hopper, communicating with a bucket conveyor, which takes the ashes up into an overhead hopper from whence they can be loaded into carts and taken away.

The illustration herewith gives a good idea of the arrangement as described above. The coal consumption is about 300 tons per day during the year. On the same floor under the boilers are situated the engines for driving the chain grates. There are four of these, and they are so arranged that they can be connected to any of the stokers, so that there is no possibility of a shut down through engine trouble. Each engine is in a recess formed in the boiler foundation, so that there is nothing in the way. They drive the stoker shafts through a belt.

As a general rule there are from ten to eleven of the 150 lb. per square inch boilers on the line, while there are six of the high pressure side working at a time. The others are of course down for cleaning, or on the standby. Some of the boilers which are actually on the line will be banked for a portion of the time, a tramway load being of course a very fluctuating quantity. The peak periods in Montreal are pretty much the same as in any big city, and lasting from about five in the morning till eleven, and again from four o'clock till seven, with another partial peak in the evening when the theatre crowds are going down town and later coming home.

Climatic conditions make a difference in the load at times, as they affect the state of the rails. A good clean wet rail will afford an excellent conducting material, and thus help matters out, while also giving a good grip to the wheels. When an icy slush covers the tracks both conditions for conducting and the grip of the wheels is bad, and the load thus increased. However, the central station crew develop a sort of sixth sense which tells them when demands are likely to be heavy, and it is unusual for them to be caught napping.

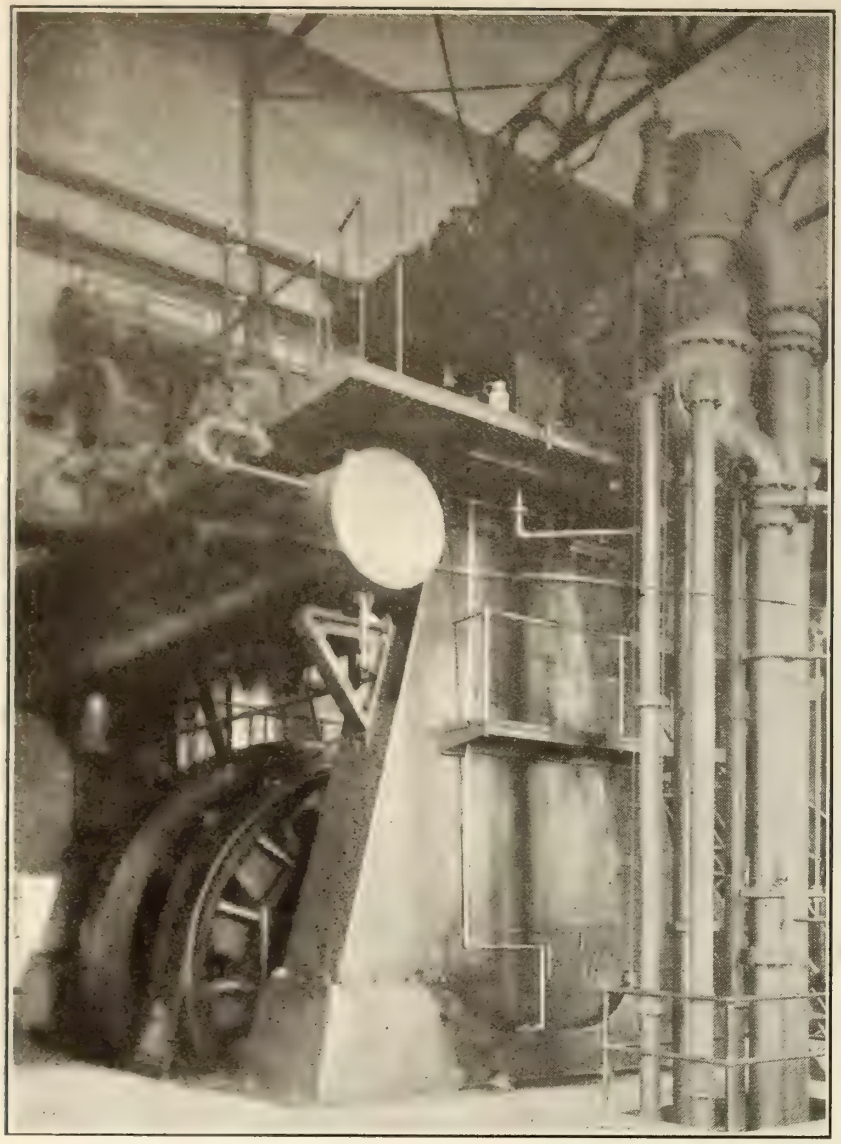
The Engine Room

The foregoing description, while it is perhaps inadequate to convey to the mind of the reader the extent of the installation, will be helped out by the photographs reproduced here, and we can go on to the engine room floor and describe in some detail the units situated up there. As we started with the low pressure battery of boilers we had better preserve the same order and start with the reciprocating units in the engine room. There are three of these, and they are all of the same type though not of the same size. The two smaller ones have cylinders of 26 inches high, and 54 inches low pressure, with a stroke of 48 inches. These two units are fitted with Westinghouse d. c. generators of 1,000 k. w. capacity, at 600 volts while the large unit has dimensions as follows: high pressure 35 inches, low pressure 72 inches with 54-inch stroke, fitted with General Electric Company d. c. generator of 3,000 k. w. capacity at 600 volts.

All these units are of the cross compound vertical type, the generators being fitted on the crank shaft between the two cylinders. They are all three fitted with barometric condensers, and work normally with a vacuum of about twenty-five inches at the condenser. There is a heater in the receiver between the high and low pressure cylinders, and the high pressure cylinder has steam supplied with a 70 deg. superheat.

The condensers are fitted with Blake dry vacuum pumps, the circulating pumps being situated in the pump room will be described later on.

The oil from these engines is taken down to filtering tanks in the basement and after being freed from impurities is pumped up into receiver tanks on the wall of the engine room, at a considerable height above the engines. One of these tanks can be seen in the illustration. The oil then flows from the tanks



View of McIntosh Seymour engine showing receiver between H. P. and L. P. cylinder and barometric condenser

to the various engine bearings by gravity, and the tanks are of sufficient capacity to contain a full day's supply for the engines. Thus a practically unlimited amount of oil under a good pressure is supplied to all the bearings. This is a very good feature and ensures good operating conditions.

It will be interesting to those who have not been in the habit of carrying out any large repairs to know that Mr. Wright, the genial chief engineer of the station, has at various times lifted the cylinders off these engines, deposited them on the engine room floor, and with a boring bar and the help of their own staff, rebored them. In most places they would be content with carrying on the ordinary duties of a plant this size but here they took on this little boring out job as a matter of course, and at a considerable saving to the company.

These three engines deliver direct current at 600 volts to the switchboard, whence it is distributed direct to the trolley wires within a certain radius of the power station. They are usually running in the winter months from 5 a.m. till 11 a.m. and again go on from four o'clock till about 7.

The 2,000 K. W. Turbo Generator.

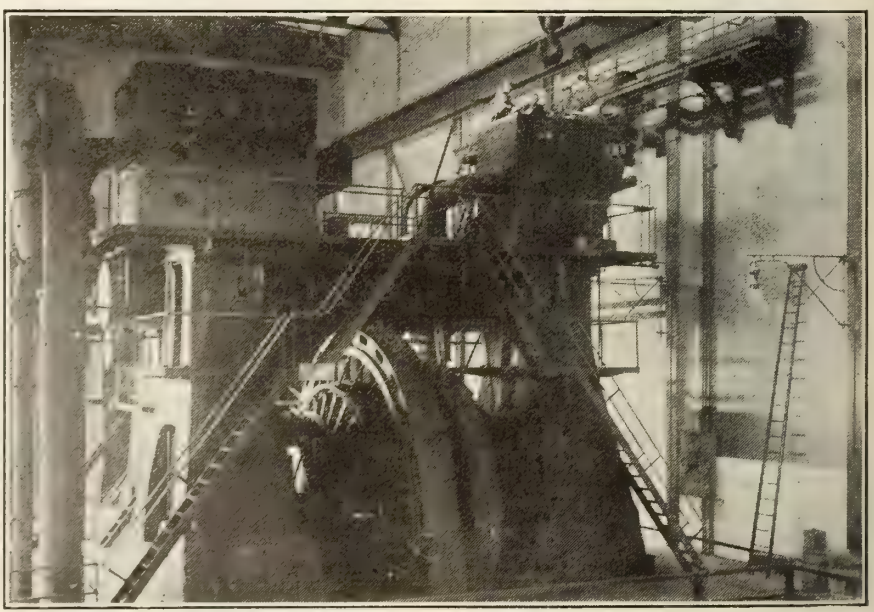
The two thousand kilo watt turbo generator which was shut down at the time of our visit, is a Bellis & Morcom impulse type turbine, direct connected to a Swedish General Electric Co. alternator of 2,000 k. w. capacity, at 2,300 volts. The condenser in connection with this unit is a Korting Multi Jet type, equipped with vacuum break, and not requiring any air pump.

There is also a small Bellis & Morcom high speed set direct connected to a d. c. generator for exciting purposes. This small unit can be seen against the wall in the illustration.

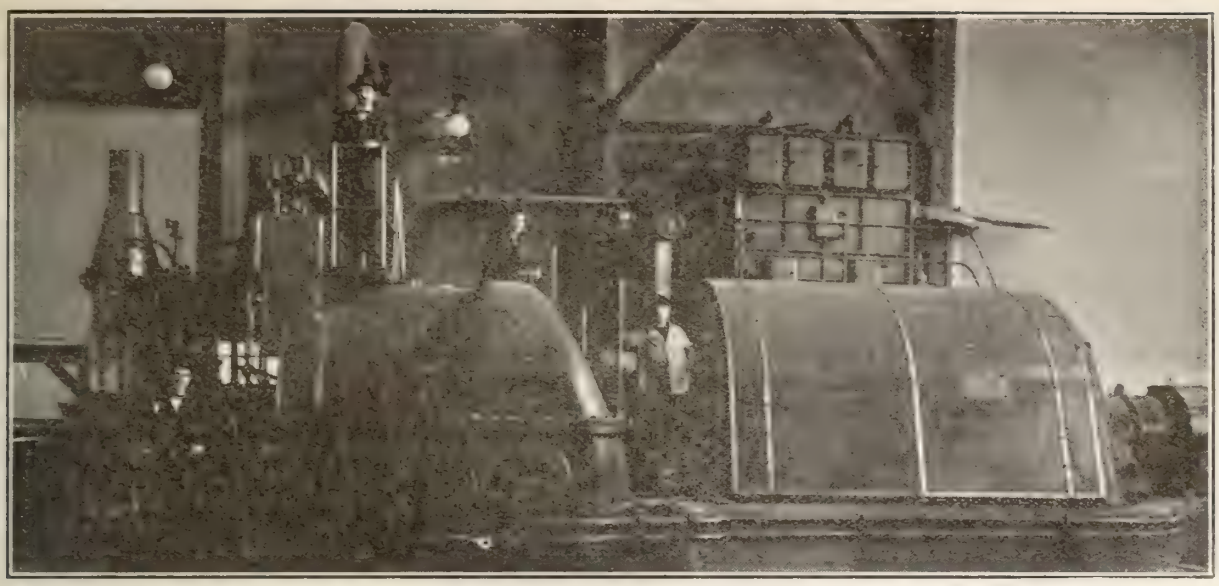
The turbine itself runs at 1,800 revolutions per minute, and is compounded for velocity at the first stage while at the second and subsequent stages it is compounded for pressure. The generator is of the revolving field, stationary armature type, and develops three phase, 60 cycle alternating current at 85 per cent. power factor, the voltage and capacity as given above.

This unit delivers power to the switch board, from whence it can be sent out to the sub-stations and used for driving the rotary converters there, or it can be delivered to the driving side of the rotary converter in the central station itself, and sent out to the trolley wires direct at 600 volts.

The ventilation of the generator, which is completely enclosed, is provided for by means of a fan fitted on the shaft, drawing air in at the bottom of the casing and discharging it at the top, after passing through the armature and field coils. The temperature rise in the windings is guaranteed not to exceed 40 deg. Centigrade after a run of 24 hours at full load, and with 25 per cent. overload for 24 hours, the temperature rise will not exceed 50 deg. Centigrade. These tem-



The 3000 K. W. McIntosh Seymour cross compound vertical engine with barometric condenser



The 12,500 K. W. Turbo Generator. The Webster feed heater can be seen behind the generator, and the cylinder of one of the Weir pumps behind the turbine

perature rises include the heat radiated from the turbine itself.

The circulating pump for this unit is a Bellis & Morcom low lift centrifugal pump, motor driven, capable of pumping 2,000 gallons per minute. The bearings of the turbine and generator are lubricated by forced feed from a pump fitted in the pedestal, and furnishing oil under a pressure of 40 lbs. per square inch to the bearings. The oil after going through the bearings is passed through a cooler before being again pumped up.

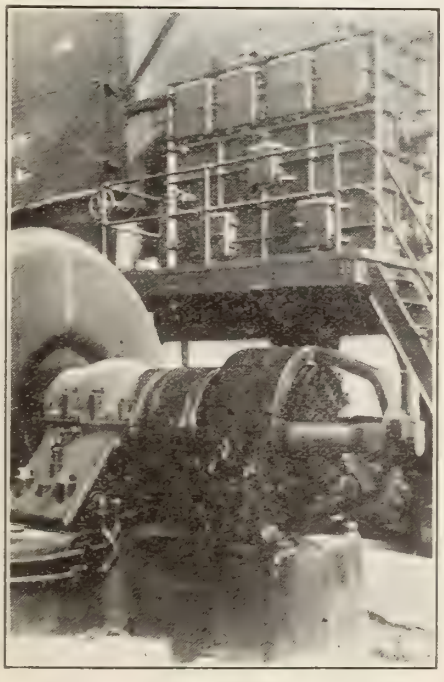
The main governor for the turbine is of the Bellis & Morcom centrifugal type, driven by worm gear from the main shaft. The emergency governor is quite separate from the main governor, and is fitted to the main shaft of the rotor. The governors operate relay oil systems, and the emergency governor is arranged so that it will close at a prescribed overspeed, or will also close if the oil pressure should fail, and it can also be tripped by hand.

This turbine is also fitted with a Mitchell thrust block, and in addition there is a safety ball thrust, which only comes into play in case of the normal bearing seizing. The coupling between the turbine and generator is of the flexible type, the flexible half being on the turbine shaft. In order to keep the casing in alignment when lifting the top half off for repairs, pillars are provided which keep the casing from any lateral movement until clear of the blading. Similar pillars to these can be seen in the illustration of the large turbine unit.

The 12,500 K. W. Unit

The next unit that engages our attention is the 12 500 k. w. General Electric direct connected turbo generator, running at 1,800 revolutions per minute, and delivering 3-phase 60 cycle current at 2,200 volts to the station switchboard, from whence it can be delivered through step-up transformers to the sub-stations and also to the central station rotary converter. The exciter is built on to the shaft of the rotor.

The turbine is a Curtis type, nine stage horizontal high pressure, working at an initial pressure of 200 lbs. and 190 deg. superheat, and exhausting to a 29 inch with a 30 inch barometer. It is provided with forced lubrication on the bearings from a pump driven by gearing from the shaft of the rotor, and delivering oil at a pressure of about 35 lbs. per square inch to the bearings of turbine and generator. Governors for both ordinary speed regulation and emergency trip are provided. For keeping the temperature of the generator windings within limits a very complete ventilating arrangement is installed. The generator is completely enclosed, as is usual in this type of installation, and air is forced through the windings by means of a fan contained on the rotor shaft.



View showing exciter on the end of rotor shaft of 12,500 K.W. unit, and Webster feed heater above.

The air ducts are so arranged that air can either be taken from the engine room or from the outside, and in the basement under the generator a complete air washing and tempering installation is fitted. This ensures that air absolutely free from dust or grit is supplied to the machine, and also that it can be delivered free from moisture which might cause sweating on the generator frame or the windings.

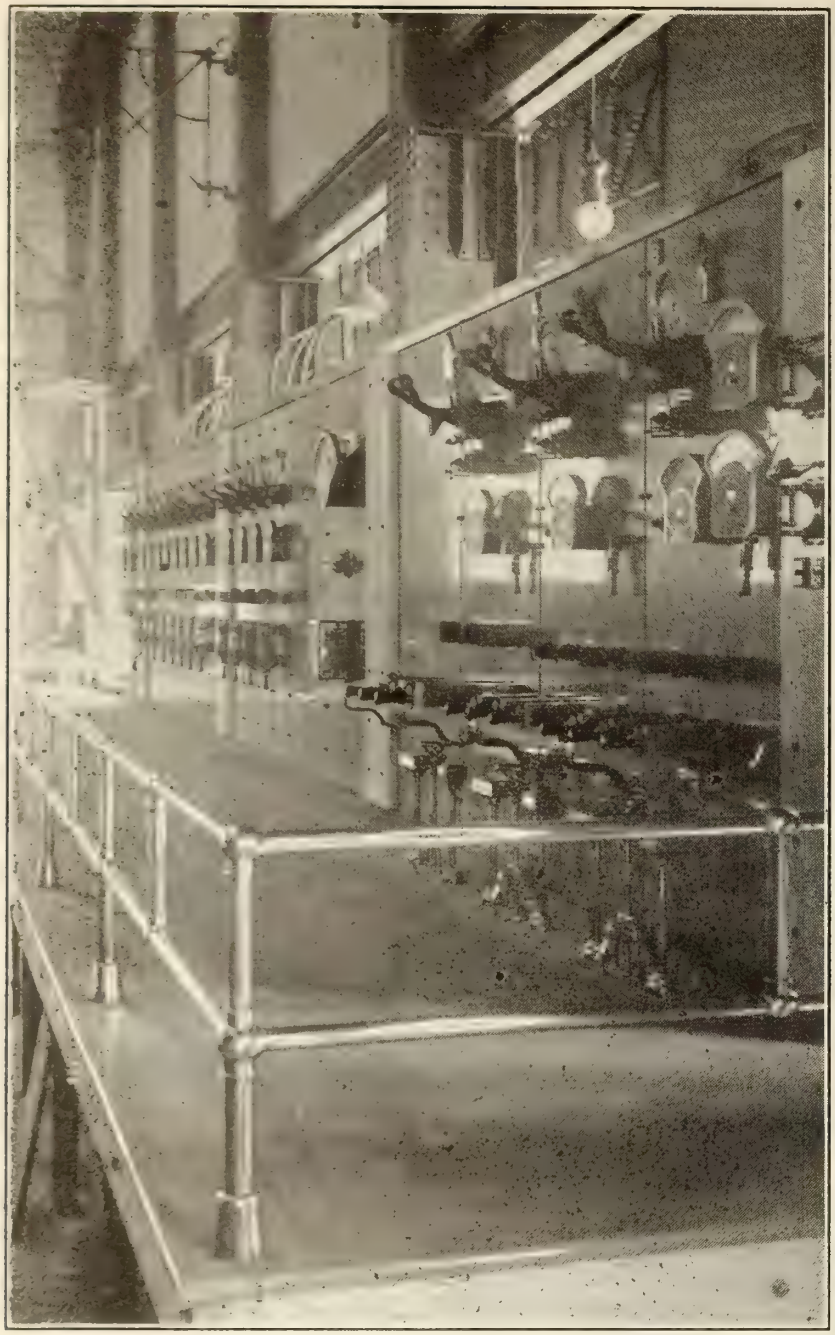
This unit is naturally the principal one in the station to-day, with its capability of such a large part of the total load. It is significant that the Montreal Street Railway are installing a second unit of the same size, which will be placed in the power house during the coming summer.

The condensing arrangements for so large a unit are naturally a source of interest, and rightly so. The exhaust steam from the last stage of the turbine passes to a condenser of the "Spiroflo" type, made by the Alberger Pump and Condenser Co., and fitted with Wheeler "Radojet" air pumps for maintaining the vacuum.

The circulating pump for this unit is an Alberger centrifugal pump driven by Terry turbines through reducing gears. The pump has a suction valve of 40 inches and a delivery of 36 inches. The delivery valve is controlled by a hydraulic cylinder, the suction sluice valves being worked by motor from the engine room.

The circulating pumps for the 2,000 k. w. unit and the barometric condensers have been arranged by the chief engineer in such a manner that any pump can discharge to any condenser, by an ingenious arrangement of by-passes. These necessitated a considerable amount of work in the way of pipe fitting, but the result achieved is excellent.

The condensate is of course used for boiler feeding, and here again we find the chief engineer has been using his initiative. For delivering the condensate



View of the switchboard, D.C. panels this end of gallery

to the heaters there were two Alberger volute pumps, single stage, arranged to works separately. Due to the somewhat high head they had to work at, there was some difficulty in handling the condensate, so Mr. Wright simply led the discharge of one pump to the suction of the other, and made a two stage arrangement of it, which got over the difficulty in great style.

These pumps then deliver to a Webster open heater, and from the heater there are two sources of supply to the boilers. One feed pump is a three-stage volute Alberger unit, driven by Terry turbine, while there is also an installation of two Weir compound vertical feed pumps, with a capacity of 18,000 lbs. per hour each. The heater and a portion of the pump can be seen in the illustration.

The Rotary Converter

There is a 2,000 k. w., three-phase 60-cycle Westinghouse rotary converter in the station, which can be operated either from the company's water power when that is available or from either of the turbo generators in the station. This converter with its motor-driven exciting unit, is situated in the east end of the station, close to the switchboard, and the transformer banks. The current coming from the water power is stepped down in the station to 2,200 volts, and the rotary converter takes alternating current at this voltage on the a. c. side, and delivers 600 volt direct current to the switchboard from the d. c. side, which is available for distribution to the trolley wires. There is also a small motor generator set on the engine room floor close to the rotary converter which is used to charge a set of Edison storage batteries, used in connection with the station signal lights.

The Switchboard

The main switchboard is situated on a gallery which extends for about half the length of the power house. At one end is situated the chief engineer's office, the rest of the gallery being entirely occupied with the panels.

At the west end are situated the three panels for the three reciprocating d. c. generator sets. Immediately next to these is the panel for controlling the rotary converter. Then come the feeder panels for the various 600 volt circuits, and at the far end the panel for the 12,500 k. w. unit. The panel for the 2,000 k. w. unit is situated on the engine room floor, and here also is the board for controlling the station lights and power circuits. Every panel is completely equipped with instruments and signal lights.

An interesting feature is the means of communication between the switchboard attendant and the assistant engineer on the floor on whom devolves the duties of starting up the d. c. units as they are required.

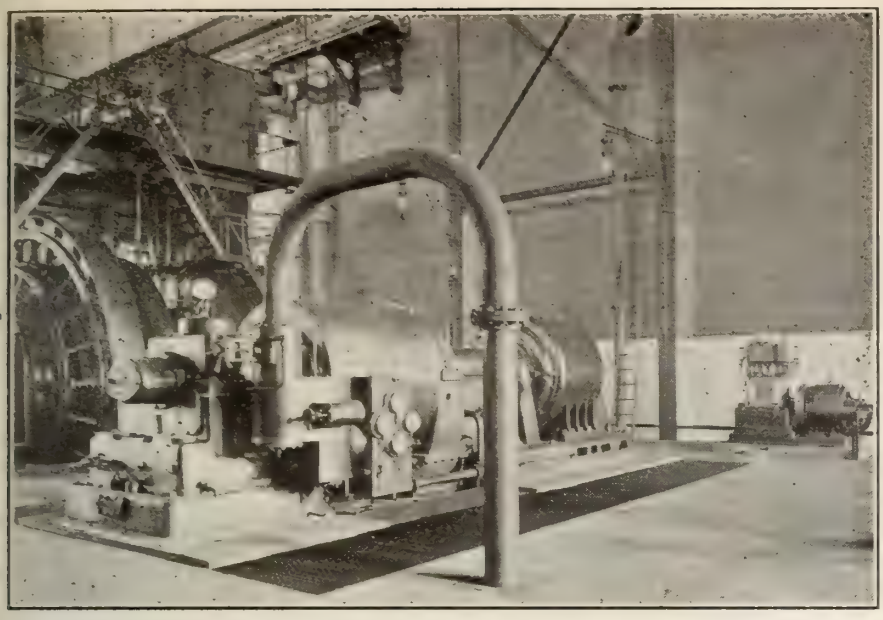
At each panel of the switchboard connected with the d. c. units is an instrument very similar to the telegraph used on board ship. It contains a dial on which are marked the words "stand by," "start," "full load," "slow," "finished."

There is a similar dial on the wall alongside each engine, and each order is illuminated with an electric light. When the switchboard attendant sees the load creeping up, he presses the stand by button and the light on the engine indicated immediately lights up and warns the attendant to get his engine ready. After a reasonable time the switchboard signals start, and the engine is started up and gradually brought up to speed. When the switchboad man has adjusted the load on his board he signals full speed and then the engine man knows his engine has got her load, and he can make his necessary adjustments. The same procedure is gone through as each engine is called into requisition, and when the load is dropping off, "standby" is signalled again, and the attendant gets ready to close down his engine as soon as the finished signal is flashed over to him. This system eliminates any confusion and running around, and saves either the switchboard man or the engine man leaving their particular duties for a moment.

Operating Features

To the operating engineer the details of operation are of as much interest as the details of the units used. The method of carrying on a plant of this kind is naturally somewhat different from that adopted in the smaller ones where one or two men perhaps carry on the whole job.

The plant is run in three shifts, and each shift has a complete operating crew, who have nothing to do with maintenance or repairs. There is a shift engineer in charge, and this man has to be a holder of a first-class certificate. This



The 2,000 K. W. Bellis & Morcom Turbo Alternator. The exciting unit can be seen against the wall.

engineer keeps a general supervision over the engine room, boiler room, and pump room, and is the executive officer for the rest of the crew. He has an assistant engineer, who looks after the starting and stopping of the various units in the engine room, and sees that they are running in good order as regards lubrication, etc. There are in addition three oilers, who find plenty to do with the various units. There are two switchboard attendants and two dynamo attendants, and this completes the operating crew in the engine room itself. Out in the boiler room there are two firemen and two helpers, which is a very small crew for the size of the plant, but this is made possible by the labor-saving arrangements in force.

There are in addition to the operating crew the repair men, but their number varies of course with the actual amount of work in hand. For instance, when a little job like lifting down a low pressure cylinder and boring it out is under way, there will be a little more help needed, than in the ordinary course of events.

The demands on the station as we have said are fluctuating, and therefore the various units have their times on and off. We may take a time in the slack hours of the morning, when probably the rotary converter will be carrying the small load on the line. The 12,500 k. w. unit will be running along light, ready to take up the burden at any moment. Soon the load begins to increase, little by little, and the large turbo generator is put in. The morning goes on and the workmen start out, calling for more cars, and more power. About five in the morning the smaller units are put in, one at a time and they carry on till probably eleven o'clock in the morning when the station is back again to the 12,500 unit and the rotary converter. This period of comparative quiet goes on until four o'clock in the afternoon, when the load starts creeping up, and the smaller units are again called into play, till about seven o'clock, when the demand slackens off.

It will be seen that there is but little idle time comparatively, and when the demand is on, everything has to be kept going. The units are at times operating under a considerable overload, and it is a not uncommon thing in street railway service, to get a sudden jolt that makes everything in the station jump for a moment. It is no place for a nervous man, that is a sure thing.

The Chief Engineer

Mr. Henry Wright, A. M. E. I. C., the chief engineer of the station, is well known to readers of Power House through letters from him and other contributions that have appeared in these columns. Mr. Wright learned his engineering in the British Navy, a very efficient school, and served in many parts of the world. He has been in the employ of the tramway company for a good many years, and has been prominently identified with educational work for the junior engineers through the Montreal branch of the C. A. S. E., of which lodge he is president. He is also Grand Vice-President of the organization, and is keenly interested in all work for the promoting of a higher standard among stationary engineers. He is himself of a very studious nature, and his home at Cote St. Paul contains a very complete little engineering reference library, of which he thinks quite a little.

Mr. Wright has a big job, which he carries on in a big way, exercising a keen supervision over the general operation of the plant, and training his staff to look efficiently after the details. He is an interesting man to talk to, and possesses a fund of information which is always on tap for those who are genuinely interested.

The writer feels that this article but inadequately covers the subject, but to enter into the subject in all the detail which he would like to, would occupy a whole issue of this magazine, which could hardly be allowed. If there are any points on which readers would like further details, the writer is sure that Mr. Wright, through Power House would be glad to supply them.

BOOK REVIEW

We have received from the D. Van Norstrand Co., 8 Warren Street, New York, a copy of "Operating Engineers' Catechism of Steam Engineering," by Michael H. Corston. The book, as its name would imply, consists of a series of questions and answers covering the whole range of steam engineering, from a practical standpoint. The subjects of heat and steam are dismissed with a brief eighteen questions, while the various types of boilers with illustrations of some of them occupy a series of 58 questions and answers. There are twenty-two chapters altogether, and the book makes a fairly comprehensive reference book for the beginner or the student of power plant engineering, or for the practical man who may be studying for the lower grade certificates. The author would have increased the usefulness of the book had he illustrated it more freely.

BULLETINS

The Mid West Engine Company, Andersen, Ind., have issued several bulletins descriptive of their various products, which include steam turbines, multi-stage centrifugal pumps, and single stage centrifugal pumps for deep well and other purposes.

* * * *

The United Conveyor Corporation, Chicago, have issued Bulletin No. 105 describing and illustrating the steam jet conveyor for ashes made by them. The various units comprising the conveyor are illustrated and several views of typical installations are given.

* * * *

The Murphy Iron Works, Detroit, have issued a bulletin describing their M. I. W. suspended arch, in which each brick is supported independently and can thus be removed or replaced without interfering with any other brick in the construction. The bulletin contains five pages, illustrated, showing the construction of the arch both in general and detail.

* * * *

The Combustion Engineering Company have issued a bulletin describing their type K stoker, which is recommended for boilers up to and including 200 H. P. The stoker is of the underfeed type, and is a modification of the type E stoker of the same company. The stoker can be regulated as to feed either automatically or by hand. The bulletin gives a detailed description with elevation and cross section of the arrangement, which makes it quite clear.

The Gasoline Engine In Municipal Plants

The Small Town Pumping Station Has Gone Through a Process of Evolution in the Last Few Years, and the Latest Practice Shows a Complete Change From the Old Steam Plant

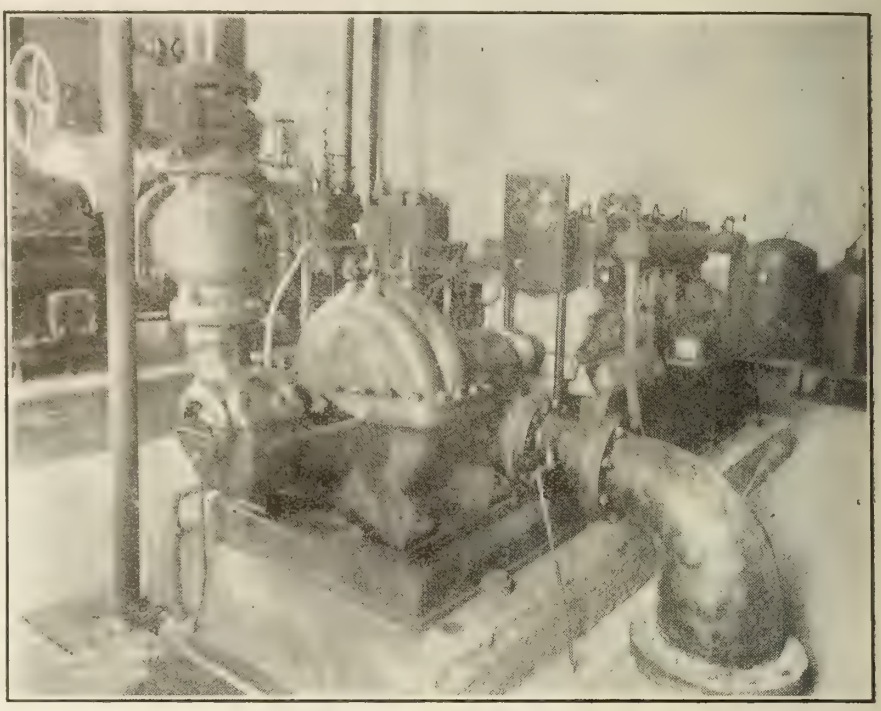
THERE has been of recent years an interesting development in the small municipality waterworks system. This has been in the nature of the standby equipment for the pumping station, which in past times, was invariably composed of a steam boiler and steam pump. In many cases this is being superseded in favor of the high speed gasoline engine, which can be direct connected to the main pumping unit in the station, through the medium of a clutch.

The pumping stations of these small towns have gone through a distinct process of evolution, from the days when the plant invariably consisted of duplex reciprocating pumps, connected to a high level storage tank, and supplied with steam from one or two horizontal return tubular boilers. With the introduction of hydro electric power, the main pumping unit became a centrifugal motor driven pump, and in order to provide for periods when there was no power available, such as occasions of electrical wire break downs or motor trouble, a steam plant was installed to take up the burden when necessary.

The straight steam station was quite an expensive proposition for the tax payers of the small town, for besides the high initial cost of the installation, the maintenance and labor cost was high. The efficiency of the plant was as a rule very low, partly on account of the class of labor which the municipal councils considered good enough to take care of their property, and partly because of the nature of the installations themselves.

In most cases, the actual pumping time of the station would be a very small portion of the twenty-four hours, under ordinary circumstances. The possibility of sudden emergency however, necessitated steam being kept handy on the boilers at all times, and the same possibility occasioned the presence of an engineer throughout the twenty-four hours. In some cases one man lived on the premises, and did the pumping, maintenance, and emergency work himself. In others, the work was divided into two shifts of twelve hours each. In either case, the expense in proportion to the actual pumping performed was high.

While some of these waterworks plants were kept in a condition highly creditable to the men in charge, it is unfortunately true that a very large number were allowed to sink into a state bordering on decrepitude. To this cause can be assigned a good many disastrous fires, which would have been easily checked had the pumping plant been able to perform its duty promptly and well. Sudden demands on a plant in which even the most ordinary necessities of overhauling have been neglected, will invariably produce disaster, and many little towns throughout Canada, have paid for this knowledge by seeing half of their property or in some cases all of it go up in smoke some fine day, when they were least expecting it.



Pembroke, Ont., Water Works.

The Motor Drive

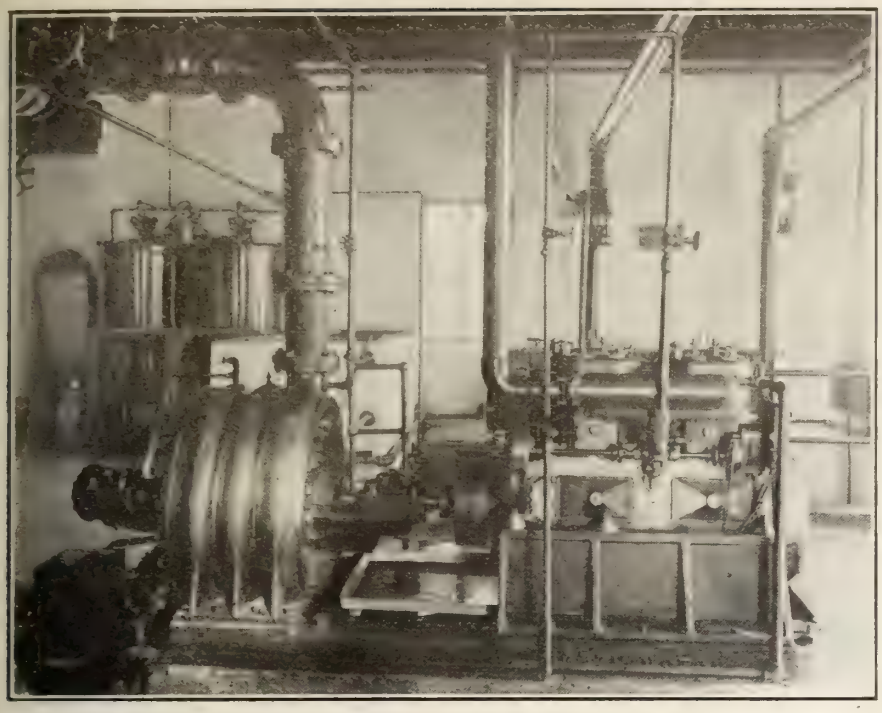
The gradual introduction of electric power at reasonable rates into all sections of the country, together with the development of the multi-stage centrifugal pump, capable of delivering water in large quantities and at high pressures, led to a great change in the small water works plant. The motor driven pump made a compact installation, and moreover one that was very simple of operation. The mere throwing in or out of a switch was all that was necessary to start or stop, and once started, it required practically no attention. However, as already stated, there were times when due to a variety of causes, no power was available, and as these times could not be foreseen, it was necessary to have a standby plant which was independent of the electric power.

The natural thing then was to install a steam pumping unit, usually consisting of one steam boiler, and a duplex pump of the type known as the Underwriter, and usually capable of delivering about 1,000 gallons per minute or enough to keep 3 streams going through 1⅛ inch nozzles. In order that this steam unit should be readily available, it had to be kept under banked fires, but in many cases, this was not done as a regular thing. Even under banked fires there would inevitably be some delay before the unit could be put into action. Where there was a reserve such as a high level storage tank this was not of such importance, but where the water was delivered direct to the mains, delay was of course dangerous. The ideal unit for emergency obviously was one that could be started at a moments notice, and be ready to pick up the load as soon as started. The logical outcome of this necessity was the recourse to the internal combustion engine, which possessed all the qualifications needed as far as reliability, ease of starting, and instant readiness for emergencies.

As the centrifugal pumps used in the water works are usually of high speed, and the usual heavy oil engine is of comparatively low speed, the use of Diesel engines would necessitate some form of reducing transmission between the pump and the engine. On the other hand the gasoline engine is essentially a high speed engine, and in addition, makers of gasoline engines have a much wider experience behind them than the heavy oil engine makers can claim, up to the present.

The Gasoline Engine Drive

The Sterling Engine Company of Buffalo, N. Y., having developed the gasoline engine for marine purposes to a high state of perfection, turned their attention to building a unit for municipal



Installation at Berthierville, P. Q.

water work and fire protection purposes, and have made many installations in Canada and the United States. We illustrate herewith a couple of typical installations in this country, together with a brief description of them.

The first illustration is of an installation at Berthierville, Quebec, and consists of a Sterling Model F 75 B. H. P. gasoline engine direct connected to a three stage turbine pump capable of pumping 900 U. S. gallons per minute. The pump was made at the Caledonia Iron Works, Montreal. The suction and discharge pipes are each 6 inches in diameter, and it delivers the water at a pressure of 125 lbs. per square inch. The engine is of the four cylinder type, and these engines are fitted usually with an electric self-starter. To make sure there will be no failure of the ignition system, there is a double ignition system installed. The plant at Berthierville was designed and installed by the New York Jewell Filtration Co., Montreal, and the engine was supplied by the Pyke Motor & Yacht Co., Montreal.

The second illustration shows the installation at Pembroke, Ontario. In this case the unit was installed to supersede the steam plant, the large steam pump being visible in the background. The engine and pump are in this case direct connected, the engine being a Sterling, and the pumps installed by the Turbine Equipment Co., Toronto.

These two illustrations show the general arrangement of these pumping plants and they are becoming quite prevalent among the smaller municipalities throughout Canada. The town of Dresden, Ont., has a typical installation of electric and gasoline driven pumps, the description of which was furnished us by the installers, Messrs. Lawrence & Lamb, of Dresden. There are two 4 inch single stage double suction centrifugal pumps, made by Fairbanks Morse, direct coupled to 25 H. P. induction motors. The pumps work at a capacity of 500 gallons per minute and a discharge head of 110 feet. They can be worked singly or in series, and for fire fighting purposes have a capacity of 110 lb. per square inch on four 1¼ inch nozzles. They can be started in less than a minute.

In case the hydro current fails there is a separate pump direct connected to a gasoline engine. This pump, is a Fairbanks 3 inch two-stage pumping 600 gallons per minute against a pressure of 90 lbs. per square inch. The engine is a Sterling F. C. 4 100 H. P. unit, equipped with an electric self starter, and double ignition, as is the usual practice with this type of engine.

These engines have some excellent performances to their credit in the way of long continued runs under heavy duty conditions, some instances of which we may give in a future article.

NEW SHAFT COUPLING

An ingenious method of coupling shafts for power transmission has recently been devised by the Coventry Chain Co. of Coventry, England. It comprises a double chain, i.e., two chains side by side, which passes round toothed flanges on shafts which it is desired to couple. The coupling is readily made by a bolt passing through adjacent links connecting up the two ends of the chain in the usual way. The coupling has a very high factor of safety, it is perfectly balanced, being machined all over, and does not require any lubrication.

The facility for disconnecting the shafts will be apparent, and the method gives a large number of possible adjustments by which one shaft may be angularly set relative to the other through the medium of the teeth into which the rollers of the chain are fitted. Although this coupling is not designed to replace universal joints it is obvious that a measure of flexibility is obtained, and it is stated that the coupling can be used to couple shafts with a deviation in angular movements of two degrees.

Relative end movement between the two shafts is also provided for, limited to about 1-16th of the shaft diameter. A special application of this chain coupling is with regard to automobiles, particularly in such cases as that of the magneto shaft where angular adjustment is sometimes required and where a slight flexibility is considered advantageous to avoid transmission of small vibrations. The coupling is manufactured in fifteen sizes which have been completely standardized, the largest type being capable of transmitting 180 h.p. at 100 revolutions per minute.

OFFSET SCREW DRIVER

Machine screws that have screw-driver slots in them often present a rather awkward problem when it is desired to screw in or remove them, owing to the location of the screws close to a wall or other projections. To overcome such conditions an offset screw-driver has been designed. Each screw-driver consists of a handle having a square forged end. On the four sides of this squared end are long narrow projections with which the slots of screw heads may be engaged. When using the screw-driver the handle is held at right angles to the axis of the screw. The projection that engages the screw-driver slot on any one side is at an angle of 45 degrees to the projection on each of its adjacent sides. Therefore if a screw is located in a cramped position, after turning the screw as far as space will permit, the screw-driver is given a quarter turn about its own handle axis by the fingers and is again applied. The screw-driver will put in or withdraw screws if only a one-eighth turn is possible. The design also has the added advantage that a considerable leverage can be applied to the screw if necessary. The manufacturers of the offset screw-driver are the Porter Products Corporation of Syracuse, N. Y.

BOOK REVIEW

The "Coal Manual" is the title of a book issued by the National Coal Mining News, Cincinnati, which deals with coal from all the aspects which are of use to a purchaser and user of this universal fuel. In addition to chapters on the analysis of coal, other chapters deal with the efficient burning of coal, and there are instructions to firemen and engineers. The book, which is published at $2.50 in the U. S., should be a valuable one for purchasing agents, plant managers, and engineers in general.

Heating Buildings By Reversed Heat Engine

The Process First Pointed Out by Lord Kelvin, as a Thermo Dynamic Proposal, is Here Fully Described and Illustrated. The Author Makes The Idea Very Clear

By F, B. MORLEY, D,Sc., M.I. Mech. E.

By Courtesy of "The Engineer."

LORD KELVIN, in 1852, pointed out that in heating a building by the burning of coal, while it might be thought at first sight that the ideal limit of efficiency would be attained if the whole of the heat of combustion were delivered to the air in the building, this was not the case. He went on to describe an indirect process employing a heat engine and a "warming machine" driven by the engine, by means of which the heat delivered to the building might be much greater than the heat of combustion of the coal consumed. So far as is known, his proposal has never been put into practice, but has remained an interesting thermo dpnamic speculation.

In these days of pressing need for conservation of fuel resources, attention has been re-directed to Lord Kelvin's idea, and in his James Forrest lecture on "Coal Conservation," in 1920, Sir Dugald Clerk stated that in his opinion, the practical difficulties which stood in the way of its application could be overcome. He again referred to the scheme in a recent lecture in Manchester, and mentioned that he understood that certain engineers were now engaged in developing it into a practical form. It may thus be of some interest to recapitulate and explain Lord Kelvin's proposal and to discuss its theoretical possibilities and the nature of the difficulties to be overcome in its application.

It being desired to pass into a building a supply of heated air, it is convenient that the air to be heated, be itself the working substance in a reversed heat engine or warming machine. The machine would have two cylinders, which Lord Kelvin called "ingress" and "egress" cylinders. We shall refer to them as "motor" and "compressor," since the air does work in the former while work is spent on compressing it in the latter. The cycle of operations would be as follows:—Air from the external atmosphere would be admitted into the motor cylinder for part of the stroke, the inlet valve would then close and for the remainder of the stroke the air would expand, falling in pressure. The drop in temperature during the expansion would be reduced as much as possible by making the motor cylinder of highly conducting material with a large surface for heat transmission. On the return stroke the air would be discharged into a receiver, also designed to encourage heat transmission and having its external surface exposed to the external atmosphere or, better still, to a stream of water. The intention, in fact, is to obtain as nearly as possible isothermal expansion and to obtain in the receiver air at a pressure below that of the atmosphere and as little below the outside air temperature as possible. The receiver might well take the form of a coil of pipes as shown diagrammatically in Fig. 1. As the object is to obtain warm air finally, the warmer the air is in the receiver the better, provided the receiver temperature is not obtained by the expenditure or electric motor.

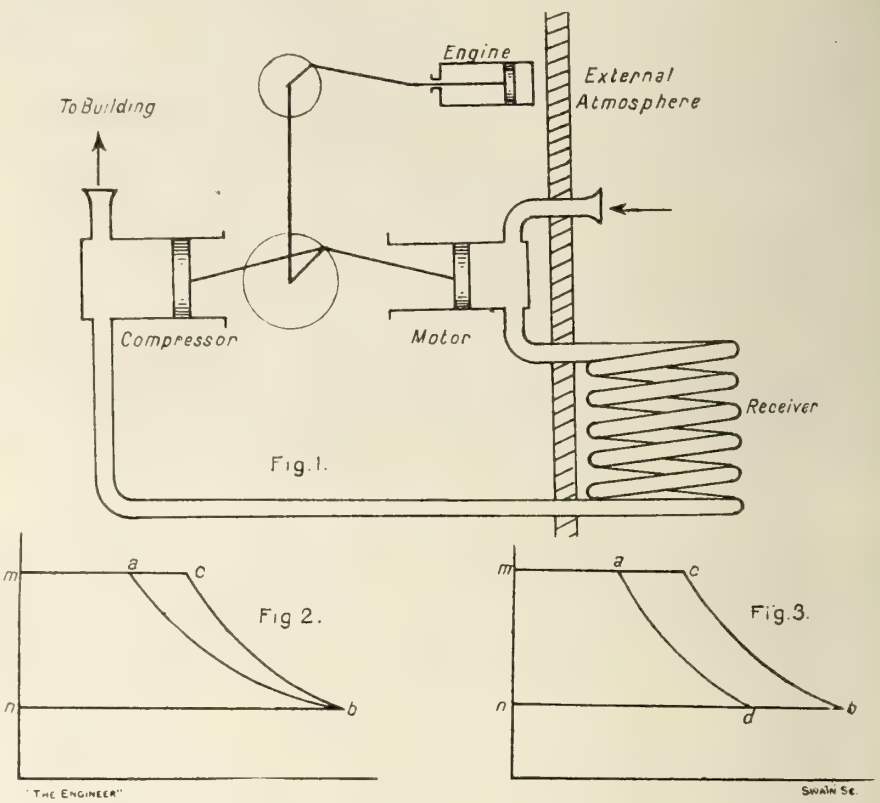


Diagram of Heat Cycle

The low-pressure air would then be passed into the compressor cylinder and would be delivered into the building. Fig. 1 shows diagrammatically the arrangement of the apparatus. The work spent on the air in the compressor would exceed the work done by it in the motor cylinder, the difference being supplied by an independent engine, water motor or electric motor.

The indicator diagrams for the process would be as shown in Fig. 2 or Fig. 3. In Fig. 2 it is assumed that the expansion is isothermal; the motor diagram is m a b n and that of the compressor n b c m. Fig. 3 is for the more likely case in which the expansion and is not isothermal, but in which the original temperature is regained in the receiver, the air therefore increasing in volume in the receiver from n d to n b. The point b n b c m is the same as before.

Lord Kelvin took as an example the heating of air from an external atmospheric temperature of 50 deg. Fah. to a final temperature of 80 deg. Fah. and calculated that by means of an ideal machine 1 lb. of air would be delivered per second with an expenditure of 0.283 horse-power for driving purposes. The heat equivalent of this power is 0.2 B. Th. U. per second. The heat required to warm 1 lb. of air from 50 deg. to 80 deg. Fah. is about 7 B.Th.U., so that the heat given to the air would be thirty-five times the heat equivalent of the work spent.

As a means of supplying the driving power, Lord Kelvin contemplated a steam engine capable of converting into work one-tenth of the heat generated by the combustion of coal, so that the effect of the whole combination would be that the heat imparted to the air would be 3.5 times the calorific value of the fuel. Modern steam plant of the best type has, of course, a much higher overall efficiency than one-tenth, amounting to 16 to 17 per cent. or even higher in especially good power stations, and internal combustion engines have a still higher efficiency. Thus after allowing

for losses of power and heat in the warming machine arising from friction and imperfect heat transference, it would appear probable that, by the method described, useful heating effect in the warming of air could actually be obtained with the expenditure of much less fuel than would be required to obtain the same effect by direct heating, even with the absolute elimination of all losses. Though at first sight this result is paradoxical, further consideration will show that it is in no way in conflict with the laws of thermodynamics nor, of course, therefore, with the law of the conservation of energy.

It has to be remembered that the heat given to the air is not all derived from the conversion into heat of the mechanical energy supplied. As a matter of fact, the bulk of the heat is taken from the atmosphere at the lower temperatures of the process. To quote Lord Kelvin with reference to the example already mentioned, "about 34/35 of the heat is drawn from surrounding objects and 1/35 is created by the action of the agent," i.e., by the conversion of the work spent in driving the machine. The function of the machine—the "agent"—is merely to bring about a temperature condition in which the working medium, viz., the air dealt with by the machine, is colder than the surrounding atmosphere or available circulating water, so that heat may thus flow from the surroundings into the working air. Then this heat, together with the much smaller heat equivalent of the driving work, passes into the building in the warm air delivered.

The process is exactly analogous to that in a refrigerating machine, having as essential elements (1) the cooling coils or cooling chamber in which heat H_1 passes into the working medium from the substance being chilled, this operation taking place at low temperature and pressure; (2) the cylinder in which the working medium is compressed to a higher pressure, work W being spent; and (3) the condenser in which the working substance at the upper end of its pressure and temperature range gives up heat H_2 to the atmosphere or to a water circulation. If W is measured in heat units, $W + H_1 = H_2$, and this is the only essential relationship between these quantities. Neither in theory nor in practice need H_1 be less than W, and, in fact, the ratio $H_1 \div W$ —termed the "coefficient of performance"—has frequently been found in tests of actual refrigerators to be as high as 9 or 10.

The idea that heat engine and a reversed heat engine working in combination may result in heat being delivered by the latter in much greater amount than that supplied to the former may be illustrated by the analogy of hydraulic machines, though the analogy is not perfect and does not constitute a proof of the relationship.

Consider a Pelton wheel supplied with a comparatively small quantity of water at very high head, and let the Pelton wheel drive a pump lifting water through a head of a few feet only. It is obvious that in spite of the inevitable losses the quantity of water pumped may be many times that supplied to the Pelton wheel since the ratio of heads is so great. The Pelton wheel is analogous to the heat engine supplied at high temperature and working with a large temperature drop; the pump corresponds to the reversed heat engine working with a small temperature range and discharging at moderate temperature. In the hydraulic case water falling from a high head is the means of raising a larger amount of water through a much smaller difference of head; so in the thermo-dynamic case, heat supplied at high temperature is the means of delivering a larger amount of heat at a low temperature.

Lord Kelvin also pointed out that the reversed heat engine could be used to cool buildings in hot weather as well as warm them in cold. In this case, referring to Fig. 1, the air flow is altered. The compressor takes in air from the building, compresses it and delivers it to the receiver, which now acts as a cooler. The operations in the compressor correspond to n b, b c, c m of Fig. 2 or Fig. 3, in which, however, n b is now at atmospheric pressure. The cooled high-pressure air is now admitted to the motor cylinder and expanded to atmospheric pressure again, the diagram being m a, a d. The temperature falls during expansion to a minimum at d and the cooled air is now delivered into the building again. This cycle has been used in practice in the Bell-Coleman type of refrigerating plant.

Returning now to Lord Kelvin's warming machine, it should be noted that the cycle he described is not a Carnot cycle, and that while in the example he gave, the heat imparted to the air entering the buliding was thirty-five times the work spent, part of this heat could not in practice be utilised in the building. The external air temperature being 50 deg. Fah., the minimum temperature in the building might be, say, 60 deg. Fah., so that of the 7 B. Th. U's. given to each pound of air in raising its temperature from 50 deg. to 80 deg., only that due to cooling to 60 deg. Fah.—i.e., 4. 7B.Th.U.—could be effective in the building, the remainder being carried away by the vitiated air. Of course, the attempt might be made to induce the air leaving the building at 60 deg. to heat the receiver to that temperature, but the impossibility of collecting all the air leaving the building as well as the difficulties of heat transmission at the low temperature differences involved would render this endeavor quite futile. In fact, it seems clear that a completely closed cycle of operations in the warming machine and the building is impracticable.

A variation of Lord Kelvin's proposal would be to take in air and compress it above atmospheric pressure, so also raising its temperature, and then circulate this warm compressed air through pipes in the building. After it had fallen to the minimum temperature permissible in these pipes, it would enter the motor cylinder, expand to atmospheric pressure and be discharged. The driving agent, as before, would have to supply the difference of the power of the compressor and the motor. If this method were adopted, however, air for ventilation would have to be separately supplied. It would seem advisable, on the whole, to combine heating and ventilation as Lord Kelvin proposed. The Kelvin method, it is to be noted, permits of the transfer of heat in the receiver being facilitated by the use of a water circulation, the heat passing from water to air rather than from air to air.

In attempting to estimate the practical possibilities of the scheme we are confronted with many points of great uncertainty. Some idea of the performance to be aimed at in the warming machine may be obtained by assuming that the heating effect of the whole plant is to be at least equal to the whole calorific value of the fuel burned. As regards the prime mover supplying power to the warming machine, it must be borne in mind that the work obtained is not the only useful effect, since, of the heat not converted into work, part may be employed for useful purposes. By the use of exhaust steam for heating purposes and also steam extracted at intermediate pressure, the total utilisation of heat in a steam plant arranged for combined power production and heating has reached in actual practice 48 per cent. of the calorific value of the coal consumed. With internal combustion engines, by the utilisation of the heat of the exhaust and of the jacket water a useful effect of over 50 per cent. has been recorded.

Speaking generally, we may assume that with a steam-driven warming machine we may obtain 15 per cent. of the fuel energy as work at the warming machine and 33 per cent. in direct heating, leaving at least 67 per cent. to be delivered as heat from the warming machine in order to bring the total heating effect up to 100 per cent. With the internal combustion type of prime mover the work may be 35 per cent. and the direct heating 15 per cent., leaving 85 per cent. as the duty of the warming machine. Thus in order to satisfy our assumption of 100 per cent. heating effect, the "performance ratio" —i.e., the heat delivered compared with the work spent—of the warming machine must be at least $67 \div 15 = 4.5$ in the former case and at least $85 \div 35 = 2.4$ in the latter. These figures, of course, might conceivably be much exceeded, and, on the other hand, even if the actual result fell far short of them, there might still be an advantage as compared with the method of heating by burning coal in open grates or even compared with using it in the furnaces of heating installations.

Calculations of the kind indicated above serve to show what the warming machine must be capable of in order to compete with other heating systems. The question as to what performance ratio we might expect from an actual warming machine is much more difficult to answer.

In the first place, it seems that the actual process would require to be pretty much on the lines of Lord Kelvin's proposal. The objections to the variation in which the air is first compressed above atmospheric pressure have already been stated. As regards the possibility of using a working medium other than air, it has to be remembered that by using air itself as the working medium ventilation as well as heating is obtained without any further expenditure either in power or plant. A reversed regenerative cycle similar to that used by Stirling in his air engine has been suggested. In the writer's opinion this cycle is not promising, since, as already pointed out, the cycle of operations required is not a closed one.

Whatever process be considered, the outstanding difficulty is the transference of heat between air on one side, at a comparatively small difference of temperature. In the absence of rapid transfer of heat the expansion in the motor cylinder does not approach the isothermal, and hence the work to be done by the driving agent is increased. Unless the air before it leaves the receiver can be brought to a temperature nearly equal to that of the external air or water supply, the heating effect of the whole process is reduced; yet to achieve this equalization of temperature or approximate to it would require either a large expenditure of power in forcing the air through small tortuous passages at high velocity or else the use of heating surfaces of very large extent. The success or failure of the method will evidently be governed largely by considerations of bulk and cost of plant as well as of mechanical and thermal efficiency.

The estimation of the prospects of success requires complete data regarding heat transmission at low temperatures, and it would appear that the first steps towards the practical development of the proposal must consist in investigations on heat transmission under the conditions indicated.

That the question of whether such a process is practicable may become one of great importance will be evident, when the dwindling fuel resources of the world are considered. Even though fuel as a source of power might be replaced by hydraulic and tidal power, the problem of keeping our houses and buildings warm in a fuelless world, to say nothing of obtaining the heat required for countless industrial processes, would still remain, and the only solution of it would appear to be the development of economical means of using power in order to raise temperature.

Power to borrow several million dollars to build a new city hall in Montreal, Quebec, may be granted by the legislature when the Montreal bill comes for final consideration before the legislative council. The old city hall which has been in use for the past thirty years was burned down early this month and the building was completely demolished. No time will be wasted in getting the new plans under way for the erection of a new city hall.

The Smoke Problem

By O. P. HOOD

Chief Mechanical Engineer, U. S. Bureau of Mines.

THE smoke problem means different things in different places. In the neighborhood of industrial plants, especially smelting plants, and cement plants, the term "smoke" is applied to material discharged, consisting of a mixture of solid particles (dust), fume which has condensed from vapors, and gases of various kinds that are produced in the operations. In the ordinary use of the word, however, "smoke" refers to the visible material which escapes from the burning of coal. White smoke usually owes its color to small drops of water which have condensed from the water vapor that is formed in the burning of coal. When smoke is black, the color is due to unconsumed particles of carbon and usually when the smoke problem is spoken of, it is this black smoke produced in the burning of coal that is referred to.

Many inquiries in regard to smoke are addressed to the Bureau of Mines, and the following brief summary has been prepared as covering the usual questions. For references to the smoke problem in England, I am indebted to a recent interesting paper on this topic by David Brownlie.

The smoke problem is nearly as old as civilization itself, for coal was being mined in Great Britain about the tenth century. In 1306, Edward I issued a proclamation prohibiting the burning of coal in the city of London, because of the "sulferous smoke and savour of the firing." In 1648, the people of London petitioned Parliament to prevent the importation of coal into the city. Beginning about 1750, when steam was applied to industrial purposes, coal began to be used more extensively, and consequently smoke became more abundant. In 1819, the Government appointed a House of Commons' committee to inquire into the matter, and another committee was appointed in 1843. Two reports were issued in 1843 and 1845. but no legislation was passed. Other investigations were made in 1846, 1854 and 1866, and finally, in 1875, the Public Health Act was passed, dealing with the question of smoke.

In the United States the problem, of course, did not develop so early, but as cities of considerable size developed here, the problem was also felt, and has been the subject of investigations, finally becoming of such importance that extensive investigations were made in Pittsburgh, Chicago and Salt Lake City. The Bureau of Smoke Regulation, in Pittsburgh, published a report in 1915, and the Chicago Association of Commerce published a large report in the same year. In the Chicago report, all the literature on the subject is reviewed, and a complete bibliography of references is given.

The black smoke which escapes when coal is burned, is due to incomplete combustion of the volatile matter of the coal. It is very difficult to produce black smoke in burning coals which are very low in volatile matter, such as anthracite. If the coal contains less than nine or ten per cent. volatile matter it is sure to be practically smokeless. It does not follow that the more volatile matter there is in coal, the more smoke is made in burning it, because the amount of smoke produced depends more on the way in which the coal is burned than it does upon the amount of volatile matter present. A coal with less volatile matter, if burned improperly, will make more smoke than a coal with more volatile matter which is properly burned. In fact, it may be said that it is possible to burn any coal without making black smoke, if proper means are adopted in its burning.

Mr. David Brownlie states, from English experience, that:

"One of the chief causes of black smoke is deficiency of draft, that is, there is not sufficient air passing through the fires to complete the combustion. Most boiler plants have cramped and badly designed flues, with chimneys too small, the usual practice being to erect a boiler plant on rule-of-thumb lines, with a chimney and main flue of scanty dimensions in the first place, and then to keep adding on extra boilers until the conditions as regards draft are hopeless. Most flues are also leaky and in a bad state of repair, which further cripples the draft. Much black smoke is, however, undoubtedly due to careless or ignorant methods of firing. If a large amount of raw coal is thrown on a fire, and then "lifted" immediately with a poker, nothing can prevent black smoke with ordinary coal. As a rule, firemen will fire one after the other the furnaces of a number of boilers, and the small amount of smoke produced by putting on the raw coal on each fire will combine to give black smoke at the chimney, just as they will persist in "lifting" all the fires almost simultaneously, causing still more black smoke. If a reasonable interval was left between the operation on each boiler, about 50 per cent. of the smoke would be prevented.

"The very earliest record we possess of any smoke-preventing device is that invented by a Frenchman named Delasme, which was exhibited at the Fair of St. Germain in 1685. This furnace is described by M. de la Hire in the 'Transactions of the French Academy of Science,' 1699, and also in Boerhave's 'Treatise on Chemistry.'

"The first reference in England to a black smoke device is that of James Watt's patent 1,485 (July 9, 1785), which was the last patent he ever took out. The patent is not very well expressed, but the general idea is to take the smoke after it has left the fire and burn it in another fire that has ceased to smoke, and so reduce the smoke by

at least half. It is not clear whether Watt understood the principles of combustion, i. e., the necessity of adding more air to prevent CO being formed, and he seems to have received more credit in the matter than is perhaps justified.

"In 1796 a man named Thompson, of whom practically nothing is known, invented definitely the coking arch of firebricks, and tried to prevent black smoke by admitting excess air on correct lines at one place only, the back of the bridge.

"In 1800 John and James Robertson, of Tradestown, in Glasgow, took out patent 2,437-1800, in which is explained in a most lucid manner the whole principle of 'coking,' whilst the same principle of coking, combined with extra heated air at the back of the bridge, was applied in 1820 by Josiah Parkes.

"Another method of endeavoring to prevent black smoke was to feed the coal regularly and in small quantities by mechanical means. The first practical mechanical stoker in the history of the world was invented by William Brunton at the Eagle Foundry in Birmingham, patent 4,387-1819, being a coking stoker with a horizontal revolving circular grate. The first sprinkling stoker, that is, one in which the coal is 'sprinkled' or thrown all over the fires was devised by John Stanley, 'a smith, in the parish of Manchester,' whose first patent was 4,692-1822. About 100 years ago, therefore, the scientific principles of combustion and the prevention of black smoke were understood and applied, and modern devices are merely developments of these original ideas."

Smokeless combustion requires the maintenance of a uniform and proper supply of fuel and air under conditions of suitable temperature, mixing and volume of combustion space. The one word "uniformity" embraces most of the ideals for smokeless combustion.

A bed of coals cannot find uniform conditions if the coal is fed in large lumps, so that powdered coal is the ideal limit for coal size. Intermittent handfiring cannot provide a uniform supply of fuel, since immediately after introducing coal into a fire a great quantity of volatile matter is distilled, calling for a large amount of air to burn it, while less air is required after the volatile matter has burned off. There is, therefore, a deficiency of air immediately after firing, and usually an excess for the remainder of the time. This cause of smoking is particularly bad when the draft is poor. Uniform, continuous mechanical feed of coal is, therefore, the ideal way to supply fuel. The intermittent firing of large amounts of coal, chilling the fire by its cold blanketing effect, and calling for heat for distilling gases, is not conducive to uniformity of temperature, so that continuous fuel feed is the ideal also from this consideration. Uniform mixing of air with the coal products is one of the most difficult things to attain. Irregular thickness of the fire, accumulations of ash and clinker in the grate, placing large amounts of coal on the fire at one time, opening of fire doors, leaky settings, all contribute to an irregular and variable supply of air when uniformity is desired, so that continuous mechanical operation aids again in approximating an ideal air supply. Uniformity in all of these things may be attained and yet a smoky fire produced, because in a small combustion space the gases may not have time to burn before they are chilled by cold boiler surface. Large combustion spaces are, therefore, necessary for smokeless combustion. With these ideals established every approach to them will tend to reduce smoke and give better combustion. The fireman that "fires little, fires often, fires quick" makes less smoke. Coal of approximately uniform size tends towards uniform fuel bed conditions.

At the present time, there are available for industrial plants a variety of designs of mechanical stoker that, when properly operated, produce smoke less combustion. But, they will, when improperly operated, produce smoke just as abundantly as improper handfiring will. In some parts of the United States, where the coal mostly in use is one that easily lends itself to the production of smoke, the smoke produced by household fires becomes a nuisance.

Salt Lake City is an illustration where the cumulative smoke of households, apartments, hotels, etc., tends to hang over the city, and is objected to for that reason. Smoke prevention in the household fire is a particularly difficult problem because the household fire is usually a small one, and the householder naturally gives it a minimum amount of attention which, of course, is conducive to the making of smoke. The simplest way to prevent the formation of smoke in household fires is to use fuel which cannot smoke even when no care is taken to prevent smoking. This means a fuel which has less than ten or twelve per cent. volatile matter in it. Anthracite coal which contains only three or four per cent. volatile matter, and coke, are admirable for this purpose. A great deal of study is being devoted, at the present time, to the carbonization of high volatile coals, for the purpose of producing a smokeless fuel. This is a mechanical and business problem, involving the use of suitable processes and equipment, so that by-products can be recovered and a low volatile coke product produced that will stand handling, and can be burned conveniently and economically.

BUREAU OF MINES REPORTS

In order to present to the public more promptly the results of its scientific investigations, the Bureau of Mines issues a series of brief mimeographed Reports of Investigations as an adjunct to the printed publications. Besides affording a medium of prompt publication of information, the Reports of Investigations provide a vehicle for the publication of briefer material which would hardly justify issuance in the form of printed bulletins. These reports deal with major metals, minor and rare metals, non-metallic minerals, petroleum, gasoline, coal, coke, safety, sanitation, mine accidents and other subjects. The reports are mailed free to interested applicants as long as the editions are available. Descriptive notices of issues in the series are mailed regularly to all who desire to receive the information. Serial 2316, just issued, is a subject list of Reports of Investigations issued to December 31, 1921, and describes some 300 repo whose range covers such subjects as abrasives, automobile exhaust gases, breathing apparatus, carbon black, Fuller's earth, liquid oxygen explosives, mine telephones, oil pipe lines, slate dust, valuation of oil properties, airplanes in mine-rescue work, powdered coal, helium, mine timbers, lead poisoning, smoke prevention, clays, building stones, safety in quarrying etc., etc. Serial 2316 may be obtained from the Bureau of Mines, Washington, D. C.

COAL STRIKE PROBABLE IN THE UNITED STATES

The following circular has been issued by the Canadian Manufacturers' Association:—

Wage agreements between the coal operators and employees in the United States expire at the end of the present month.

For some weeks there has been considerable speculation as to whether or not new wage agreements can be negotiated without a strike.

We have just received the following report from reliable sources in the United States, which is forwarded for your information:—

"Unless something unforeseen develops a suspension of operations in the bituminous coal fields of the United States will take place on April 1st. The anthracite coal situation depends on a meeting of the miners to take place in New York on the 15th instant. Industries in the United States are organizing in efforts to lay in stocks of coal before the strike may come."

Yours faithfully,
W. S. FISHER,
President.
J. E. WALSH,
General Manager.
J. T. STIRRETT,
General Secretary.

The Oakville town council has decidded on the installation of an auxiliary pump for emergency water works purposes. This will either be gasoline or steam driven.

Figures of the operation of the pulp and paper industry in Canada during 1920, just issued by the Dominion Bureau of Statistics, set forth in a striking manner the rapid growth of this branch of industrial effort during recent years. There are 100 pulp and paper mills all told; capital investment is given as $347,553,000.

Broadening Out

QUITE A LOT of conversation has been heard of late on the matter of broadening out, as applied to political parties, etc. It is a term that could aptly be applied to the stationary engineer, or as we would prefer to call him the power plant engineer. In these days the man who is able to take charge of any type of plant has to possess a knowledge which is of greater scope than was dreamed of by his not so remote predecessors.

In the case of the main driving units in the power house, or prime movers, there is a very wide variety. In this country to-day we have Diesel, semi-Diesel, gasoline, producer gas, and a few kerosene engines. We have all the divers types of Corliss valve engines, drop valve engines, high speed slide valve engines, and steam turbines. Of auxiliary apparatus there is no end, and it is continually being improved and new ideas put on the market. There is the refrigerating machinery of which again there are numerous designs, and two distinct types, the compression and absorption system. Again there are the plants which use steam for heating and motors driven from outside power to supply the power requirements.

There is no possibility of any man becoming acquainted intimately with every type of machinery and apparatus that goes into a power house. What he can do, however, is to master the underlying principles of the science of steam engineering and electrical engineering insofar as it enters into industrial power plant work, so that he can readily grasp the design and operating principle of any machinery which he may be called upon to handle. With such knowledge, built upon a firm foundation, he will never hesitate to tackle the biggest job which opportunity may put in his way. This is the method in which the power plant engineer should broaden out.

To the man who gives up the time and puts in the hard work necessary to acquiring the engineering education outlined above, there is the field of wider opportunity, which is always open to the well-informed man in any line of endeavor. He can achieve real professional status through the medium of the professional engineering societies which do not close their doors to the stationary engineer if he can prove himself capable of meeting their requirements. This again gives him the opportunity to meet and mingle with the best men in all branches of engineering, to hear the papers presented by them, and still better, to hear and perhaps participate in the discussion.

One side of the engineering profession which the average stationary engineer does not grasp thoroughly, and which is of great importance, is the commercial side. The particular branch which should interest him is the relation to the investment cost that the operating costs of the power plant bear, and how his plant would figure if he were selling power to customers instead of supplying it to the factory. After all, every power plant is engaged in the business of manufacturing and selling power, whether it is a public utility plant or a small factory plant with one boiler.

If every man who enters the boiler room as a beginner, went in with the intention of giving a certain number of years to the study as well as the practice of power plant engineering, and carried this intention out conscientiously, there would soon be a very marked difference in the status of the engineer in Canada. We fear, however, that the majority of men do not possess this spirit, but rather, are just willing to learn enough to get by with.

The attendance at the classes in the technical schools, which, like salvation, are free, does not show any wild demand on the part of the younger men for education. Of course, it may be that they are already advanced beyond the stage that the technical school classes cover, and therefore do not feel like wasting time. We would suggest to them, if there are such men in the boiler and engine rooms of the city and country, that there are still the universities, so that they need not stand still.

Heating By Electricity

A UTILIZATION of electric power, otherwise idle for certain periods, for the generation of heat is well known in Europe, where it has been used for some years. It is now coming into use in Canada and the United States. The generation of heat by electricity used for no other purpose is not an economical proposition, but when electricity is purchased at a flat rate, and would otherwise be idle for considerable periods, it becomes quite feasible. The general method adopted, is to turn the current when not in use for power purposes, through resistances which are arranged to dissipate their heat by radiation to the water in a boiler, or in other cases, making the water itself the resistance.

In heating water and converting it into steam in this manner, there is very much less loss by radiation than is the case when coal is burned in a furnace, and the losses incident to the chimney draught and inefficiency of combustion are of course eliminated. In the case of the boiler with the water acting as the resistance, the heat transfer is direct, and there are no losses.

It would seem that there is a possibility of using this method of steam generation with a system of storage. The use of steam accumulators has been developed in connection with pulp and paper mills particularly in recent times. There might be more heat available from electric power at some particular time than could be utilized at the moment. In such a case, if means were provided to store that heat in the form of steam until the demand was sufficient, we should have an ideal system.

Ideal systems unfortunately are not always practicable, and there is the question of the cost of providing storage capacity with sufficiently good insulation to make it of use. This cost might easily be more than the saving to be obtained, but the conditions at any one plant might make it feasible while at a second one it would be out of the question.

The Operators' Point of View

CLINKERLESS FIRE

By H. Gradt

In writing on this subject it will mostly interest firemen, also engineers who are doing their own firing, in a hand fired furnace.

The fire in this article will be slack coal, but if anyone is fortunate enough to be using better than slack, why this problem will be easier worked out, as the method applies to both kinds of fire. Efficient firemen do not receive the credit they deserve, as a rule, and I maintain the word "job" should be eliminated and the word "profession" substituted, to all those that are worthy and can show results.

My income since I started engineering first in Canada has been raised 157½ per cent. largely due to possessing the knowledge of burning slack. I had to make a few moves of course but each employer realized the importance of the fuel question, so if I see fit to make a few more moves I will be drawing a fair salary.

In starting my fire I never clean out all the ashes, leave about 3 inches on the grates then take a poker made of ¾ iron with a 3½ in. hook bent at right angle on one end and pull this poker back and forth on the grates with the draft on, until the coarse cinders are free from fine ashes. The fine cinders drop through the grates and the fine ashes escape through the stack. Next level the remaining cinders evenly on the grate, and pack them down evenly, which is all done with the same poker.

With a little practice this can be accomplished in a very short time. The gain is worth the trouble.

Some readers may wonder right here what is the idea of the cinder bed on the grates?

Three good reasons, viz.;—

1st.—Prevents live coal and fine fuel from falling in the ash pit.

2nd.—A fire will burn 40 per cent. better on a cinder bed than from the bare grates due to the fact that the air is more uniformly distributed.

3rd.—Should a clinker be formed it is much easier to remove it from the cinder than it would be to pry it loose from the grates.

Having the cinder bed completed, next sprinkle on some live coals, preferably with a shovel, evenly, taking care that the coals are not closer than 1½ to 2 inches. Then put on about 2 inches of slack, using a little more draft in starting a fresh fire than usual, and fire light for an hour or so, always placing the coal where the cinders start to show up. Never put green coal on a white heat fire bed, as this is the secret to avoid clinkers. After firing for about an hour you will notice the fire will burn better and quicker and then the drafts can be checked so as to maintain the desired steam pressure and the furnace can be fired heavier, say about 4 inches.

If the coal is coarse, say like the size of goose eggs, a much heavier fire will give better results. The idea is to stop excess air going through the fuel bed.

If a bluish color appears in different places in the newly fueled bed, this is an indication that there is no air passing through those certain spots and some obstruction is the cause, either fine ashes in the cinder bed, or the grates may be plugged up.

If it happens to be fine coal dust just fire around those spots and very likely next fire those spots will have disappeared.

If a dull red spot appears in a fire bed you may be sure there is the old familiar clinker under those dull coals.

If it is a new fire and not badly clinkered, by firing around those spots they may burn out in one or two fires, if not, my remedy would be to break up those clinkers so that the air will pass through them.

My definition of how a clinker is made, is by adding more fuel to a fire before it is properly burned down, thereby obstructing the air from passing through the burning coal causing it to run and glaze.

Have run a fire 15 hours on slack without cleaning the fire using only one 16 x 66 H. R. T. boiler and pulled a mill of 200 bbl. capacity and elevator attached without having any clinkers in my fire.

Particular attention is given to a new fire and when it has been burning for an hour or so and is burning clear, after that I never use a slash bar or poker as this disturbs the ash bed and destroys the porous form which the ash bed naturally forms by proper firing.

Considerable advantage is obtained by letting the coal slide from a shovel so it will fall instead of slide on the fuel bed as sliding green coal also, especially on a new fire, moves the cinders to some extent and partly closes the porous portions.

I use force draft and think it has an advantage over natural draft, as the stack draft can be checked just enough to allow the smoke and gas to escape thereby reducing the stack temperature.

The force draft can be adjusted to meet the requirements of steam consumed. The intake of the force draft in this plant is located near the ceiling of the engine room and supplies the furnace with warm air, which also is an advantage over natural draft.

Am of the opinion that anyone wishing to bring my theory in to practice will not succeed the first time completely, but practice makes perfect, and anyone wishing more information on this subject may get it through Power House or the writer direct.

NOTES ON STEEL PIPE

By James E. Noble

Sometimes the statement is made that steel pipe is greatly inferior, in lasting qualities, in comparison with wrought iron. This statement may be made by persons who have made little, if any effort to inform themselves from reliable sources as to the truth or falsity of their opinion. The truth of the matter, or what at least looks like the truth, secured after exhaustive tests of long duration, and easily available to anyone interested would seem to prove that a high grade steel pipe, of modern manufacture, is quite as good as the old reliable wrought iron. For some purposes it might even be better than the latter, and some surprising facts will often show up even in ordinary experience.

About five years ago I had a hurry call, to run to some heating coils, a steam line carrying 100 pounds pressure, the line being several hundred feet long. There was no steam pipe on hand but there was a quantity of black, compound coated 1¼ inch steel, electric conduit. I was advised not to use this pipe by men who predicted all kinds of trouble if I did so, and I was told that it would become pitted and leaking over its entire length in a short time, and that the compound would cause continued trouble by lodging under valve seats, etc. However I was used to following my own opinion until shown that I was mistaken, so, taking a chance I installed the conduit. This pipe, after five years service, is still steam tight and apparently good for a long time yet, there has been no valve trouble from the compound coating. Under certain conditions one danger there could be from using such coated pipe, that is the danger of some of the detached coating reaching the steam boilers, in the case in

question the conditions were such that this was almost impossible. In an emergency some years ago I used a considerable quantity of ½ inch and ¾ inch galvanized steel electric wire conduit for a hot and cold water supply carrying 40 pounds pressure.

This pipe is still in use and is still water tight while some ordinary galvanized iron water pipe which was installed about one year after the conduit, and which was operated under the same conditions, developed so many defects that it had to be replaced with new pipe.

OFFERS A SUGGESTION

In response to the notice to the effect that our columns would be open to suggestions from readers as to how to obtain action on the Dominion wide certificate, we have received the following letter from a correspondent:

The Editor,

Power House:

With reference to your notice in March 5th, "Power House," in regards to the "Dominion Wide Certificate," and by way of suggestion am offering the following:—Why not print a resolution as set forth below, or one of similar nature, in the "Power House," and let every engineer cut it out of his paper and mail it to you, and you in turn forward it to the proper parties who would act. Should there be any engineers who do not take the "Power House," (which I hope there are not) let him copy the resolution from his brother engineers' paper, sign and send it in. I would also advise him to send in $2 for a year's subscription to our national engineer's magazine as he does not know what he is missing if he does not take it.

The resolution I propose is as follows:

Resolved, that the stationary engineers of the Dominion of Canada, deem it in the best interests of the profession, that the certificates of competency issued to engineers, should be issued on the authority of the Dominion Government, instead of the Provincial Governments of the various provinces. That engineers at present holding provincial certificates be granted a Dominion certificate of the same grade. That we the engineers of Canada request the Grand Lodge of the Canadian Association of Stationary Engineers as the representatives of the stationary engineers of the country, to take up the question with the Governments involved.

We pledge ourselves individually and collectively to heartily support the movement financially or otherwise.

This is offered as a suggestion to start the ball rolling, and get some action.—C. T. M.

STEAM FLOW METER

Question:—Please describe a flow meter, and tell me all the data that can be secured from a steam flow meter chart.—F. H.

Answer:—There are several types of steam flow meter, which all, however, operate on the same general principles. A pitot tube, or throat orifice on the same principle as a Venturi throat, is placed in the steam pipe and the difference of pressure on the two sides of the tube are communicated to two chambers containing mercury, the difference of pressure in the two chambers causing a rise and fall of level similar to the action of the water in a U tube such as used on draught gauges. The recording mechanism is attached to floats on the surface of the mercury, and the dial of the instrument is calibrated to read in lbs. of steam per hour, or thousands of pounds per hour.

A little more detailed explanation of one or two of the principal makes may be useful. In the meter made by the Republic Flow Meter Co., the pitot tube communicates with two openings leading into individual reservoirs. The openings in the pitot tube are so placed that one faces the flow of the steam in the steam pipe, while the other opening faces the opposite direction or perhaps it may be plainer if we say one faces up stream and the other down stream, considering the flow of steam in the pipe as the stream. The steam which enters the opening facing up stream causes in addition to its static pressure, a further pressure caused by its velocity, while the pressure on the tube facing down stream is due only to the static head. The up stream tube is called the dynamic tube and the down stream the static tube. The result of the extra pressure due to velocity in the chamber in communication with the dynamic tube, is to depress the mercury, and this results in raising the level of the mercury in the static chamber, the two being connected by a U tube.

The meter body, recording instruments, and ground are included in a circuit current being supplied by a small transformer. The circuit is completed by means of contract rods which are supported in the static chamber, these rods being of different lengths. The terminal post on the meter body is connected to a series of resistances, and as the mercury rises successively touching the rods, the resistances are gradually cut out and more current allowed to flow through the meter, which increases the reading on the instrument board. This instrument is calibrated to read in units of flow.

The Bailey Flow Meter instead of using a pitot tube, uses a metal plate containing a carefully calibrated orifice, which is inserted between a pair of flanges. The differential pressure on the two sides of the orifice is conducted to the inside and outside of a bell shaped vessel floating in a chamber of mercury. The increased pressure due to velocity is allowed to act on the inside of the bell, causing it to rise, and the movement is transmitted through a lever direct to the recording dial.

The General Electric Co. make a flow meter which operates with a pitot tube the difference of pressure being transmitted to the two legs of a U tube. The recording in this instrument is achieved by means of a magnet operated from on top of the mercury column, which in turn operates a magnet on the face on the dial.

It will be understood that there are various features about all these instruments that cannot be alluded to in a general answer of this kind, and we would advise our reader if he is interested in the matter to request detailed description from the various makers.

EVAPORATION QUESTION

Question.—How much heat would be required to convert 9 lbs. water at 140 degrees into steam at 140 lbs. per sq. in. absolute, the steam being 2 per cent. wet? What is the equivalent evaporation under these conditions? If one pound of coal with a heat value of 14,500 B. t. u. evaporates this amount of water under the conditions named, what is the efficiency of the boiler?

Answer:—The total heat of the liquid at 140 lbs. per sq. in. absolute is 324 B. t. u. The latent heat for saturated steam at that pressure is 865.5, and for steam of 2 per cent. moisture will be 865.5 x .98.

The total heat will then be S plus L 324 plus 865.5 x .98.

Feed water at 100 degrees is 68 above 32 F., so that the total heat required for the conversion will be

324 plus 865.5 x .98 minus 68, equals 1,004.19 B. t. u. per lb.

1,004.19 x 9 equals 9,037.71 B. t. u.

The latent heat of evaporation from and at 212 degrees is 965.8 so that the equivalent evaporation will be as

965.8: 1,004.19 so is 1: x

which gives 1.03 as the equivalent evaporation.

The efficiency will be the total heat of evaporation of nine pounds of water from 100 degrees to steam at 140 lbs. absolute and .98 degrees dry, divided by the total heat value of one lb. coal and multiplied by 100.

$$\frac{9{,}037.71 \times 100}{14{,}500} = 62.32 \text{ per cent.}$$

A CORRECTION

In the March 5th issue of Power House, page 37, column 2, the formula for the area of the segment of a circle was, due to a typographical error, printed in a form which made it read quite wrong. The formula is as follows:

$$\frac{4 \times h \times h}{3} \times \sqrt{\left(\frac{d}{h} - .608\right)}$$

MONTREAL LODGE C. A. S. E.

Montreal Lodge, C. A. S. E. held their regular meeting on March 10th, Mr. Fenner, Editor of "Power House," was a visiting member from Toronto on this occasion, and enjoyed the opportunity of meeting many of his old friends.

By GEORGE R. ARCHDEACON, A.M.I.E.E.

AS ALREADY mentioned in the last chapter when we have a number of resistances in parallel, the total resistance of the circuit is reduced and the method of determining the total resistance is more complicated than when the resistances are in series.

Fig 1 illustrates 3 separate resistances in parallel, each resistance being a different value, as indicated by the figures against each resistance.

The following rule must now be learned:—

The combined or joint resistance of two or more resistances when connected in parallel is equal to the reciprocal of the sum of their respective conductances.

The reciprocal of a number is the inverse of that number and is obtained by dividing that number into unity.

Example:—

$$\text{The reciprocal of } 5 = \frac{1}{5} = .20$$

$$\text{The reciprocal of } 7 = \frac{1}{7} = .142$$

$$\text{The reciprocal of } 20 = \frac{1}{20} = .050$$

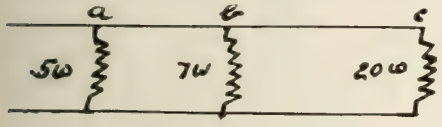

FIG. I

Substituting the resistances shown in Fig. 1 the total resistance will be as follows:—

$$\text{Total R} = \frac{1}{\frac{1}{5}+\frac{1}{7}+\frac{1}{20}}$$

Reciprocal of sum of conductances

Sum of Conductances

By adding the conductances together we obtain the combined conductance. If we now take the reciprocal of the combined conductances we have the total resistance.

Remembering that the conductance is the reciprocal of the resistance, we must add all the conductances together:—

$$\frac{1}{5}+\frac{1}{7}+\frac{1}{20} = .20 + .142 + .050 = .392 \text{ mho.}$$

As the resistance is the reciprocal of the conductance, we must now take the reciprocal of the total conductances.

$$\text{The total resistance} = \frac{1}{.392} = 2.55 \text{ ohms.}$$

Current in a Series Circuit

In any electrical circuit there is always resistance, and to overcome that resistance and cause current to flow it is necessary to have a voltage behind the current to "push" it through the circuit.

In other words, to "push" amperage through ohmage, it is necessary to have voltage. We cannot have a circuit without resistance, and we cannot force a current through resistance without electrical pressure.

The pressure necessary to send current through resistance is expressed by Ohm's Law:—

Volts = Ohm's × Amperes.

The current flowing round a series circuit will be the same value at all parts of that particular circuit.

It will be quite obvious if a circuit consists of a wire of uniform material and size, the current flowing through that wire, will be the same at all points along the wire.

Generally a circuit is not of uniform material or resistance, this often causes the student some confusion of thought as to how the current can be of the same value in all parts of such an uneven circuit. It is therefore worth our while to pause to consider this problem in a more detailed manner, and make it quite clear for all time.

Current is the rate of flow of electricity in amperes, or in coulombs per second.

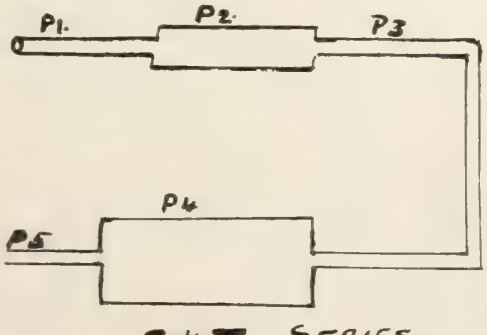

FIG. II SERIES

A "coulomb" is a definite quantity of that invisible "something" which we call electricity, (just as a pint is a definite quantity of water) and is considered to be one ampere per second.

In Fig. 2 there is represented a number of pipes connected together "in series" each of these pipes are of different diameter, and connected to a water supply, so that it flows through the whole system of piping.

The rate of flow could be expressed as so many pints or gallons per second; and it will be obvious that this rate of flow must be the same all round the system. If the rate of flow at any point in the smallest pipe is 2 pints per second, it must be exactly the same at any other point, say in pipe 2 or 3.

The reason for this being that more water could not pass by here than there is room for ahead, as water is incompressible. Therefore the rate of entry of water at the big pipe must be exactly the same as the rate of flow from the smallest pipe.

Electricity being incompressible, the above analogy will apply.

Whenever resistances are connected in parallel, the total resistance of the circuit is reduced.

This again at first glance seems rather strange, that the adding of more resistance to a circuit, results in a reduction of the total resistance of that circuit.

Let us therefore again make a water analogy. Consider each additional resistance as being an additional circuit, forming an additional pathway through which the current will flow.

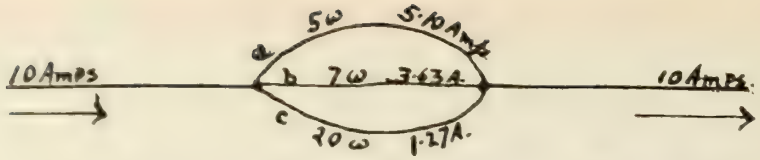
In Fig. 3 we have another system of pipes, from which it is readily seen, that the more pipes added to the system, connecting the top to the bottom of the system, the greater the rate of flow will be, from the top to the bottom, because the resistance to the flow is reduced by each additional pipe added to the system.

It will now be quite obvious that in dividing up a circuit into a number of branches, the current will vary in each branch, and such variation in current flow, will be entirely controlled by the resistance of each particular branch.

In Fig. 4 the main current is taken as 10 amps. Let us use the same resistances as calculated in Fig. 1 viz., 5 ohms, 7 ohms, 20 ohms, respectively.

To find division of main current in the branches of a circuit, when the strength of main current is given, also the resistance of the branches.

Suppose in Fig. 4 the resistance of a, b, and c, were 5, 7, 20, ohms respectively, and the main current was 10 amps.



DIVISION of CURRENT THROUGH PARALLEL CIRCUITS.
FIG IV

How much current would go through each branch?

The rule regarding the division of current in such cases may be stated as follows:—

When a continuous current divides to flow through two or more parallel branches in a circuit, the fraction of the total current in each branch will be directly proportional to its relative conductance.

1st Step.—The resistance of each branch is 5 ohms, 7 ohms, 20 ohms respectively.

The conductance of each branch will therefore be:—

$$\frac{1}{5} = .200$$

$$\frac{1}{7} = .142$$

$$\frac{1}{20} = .050$$

and the total will be .392 mho.

2nd Step.—It may therefore be assumed that the total conductance of .392 mho is made up of 392 small units, and that 200 of these are in a, 142 in b, and 050 in c. It may also be assumed that the current splits up into 392 parts, of which 200 flows through a, 142 flows through b, and 050 through c.

The values of the currents through the three branches will then be:—

Through a, $\frac{200}{392}$ of 10 amps = 5.10 amps.

Through b, $\frac{142}{392}$ of 10 amps = 3.63 amps.

Through c, $\frac{050}{392}$ of 10 amps = 1.27 amps.

Total 10.00 amps.

Branch circuits, or parallel circuits, sometimes develop accidentally. Sometimes when a switch is turned on, the lamp fails to light, and a fuse is "blown." Upon investigation a "short circuit" is discovered. This is only another way of saying, a parallel circuit of considerably lower resistance has been established. Like most human beings, electricity always chooses the "line of least resistance," consequently whenever the parallel circuit is established, the current will rush down that avenue, if its resistance is lower than that of the main circuit.

In using an ammeter to obtain high current readings of over 10 amps, a device is used, which only allows a very small fraction of the total current to flow through the ammeter, the balance is sent round in another branch circuit. When so applied this is called a shunt, but strictly speaking it is nothing more or less than a "short circuit" whose resistance has been carefully calculated to prevent too great amount of current flowing through the circuit, resulting in possible damage to the instrument, operator, or fuses.

Frequently in the operating of the power plant it is of great importance that the current consumed by various motors, heaters, etc., should be actually measured to learn if they are operating efficiently. Upon such occasions it is necessary to connect the motor or heater, which is to be tested with an ammeter in series with the mains supplying the current. It is then most important that the correct shunt be chosen, otherwise when the current is switched on, the instrument will be burned out, and rendered quite useless.

Therefore never on any account use a shunt which has not been made for the particular instrument you are using, because the resistance of the unknown shunt will permit more or less current to pass into the instrument, resulting in errors in the reading, or even lead to the actual burning up of your instrument.

In conveying steam or water through pipes, a certain size of pipe will only suffice for a certain quantity of steam or water. Similar conditions prevail in conveying electricity along wires, only a certain quantity of current can be conveyed by a certain size of wire, if these limits be exceeded the wire will melt and the circuit be broken, and perhaps a disastrous fire result. Care must always be taken to see that the correct size of wire is chosen, and when once installed never overloaded. The carrying capacity of a wire is limited by a fixed quantity, as established by the various power companies and insurance companies. These limits are expressed as the current density of the conductor.

The current density of a conductor is expressed in amperes per sq. in.:

This may easily be found as follows:—

Let D stand for Density.

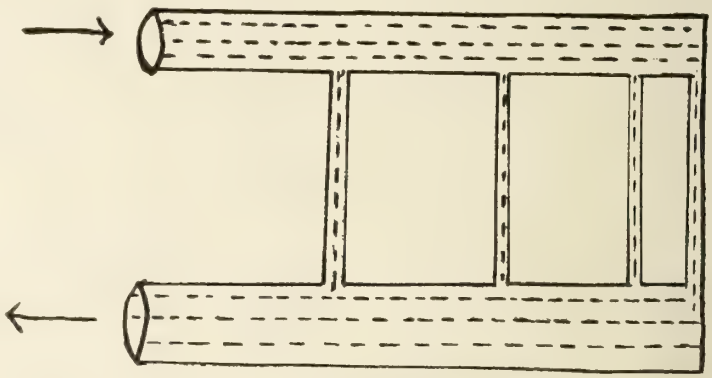


FIG III PARALLEL.

Let I stand for Current in Conductor.

Let a stand for Sectional Area of Conductor.

Then $D = \frac{I}{a}$; $I = a \times D$; $a = \frac{I}{D}$

A very conservative loading for all wires and cables is 1,000 amps per sq. in. It makes all calculations simple, and provides a fairly reasonable voltage drop.

It has already been mentioned that excessive amount of current will cause the wire to melt. It is therefore apparent that when a current of electricity traverses a wire, heat is generated.

When the heat is generated, energy is dissipated, volts are lost, and work is said to be done.

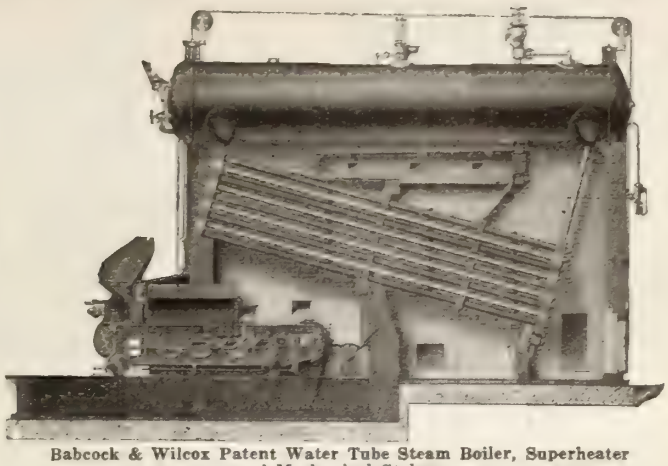
"B & W"

PATENTED

WATER TUBE BOILERS

Perfect in Construction



Babcock & Wilcox Patent Water Tube Steam Boiler, Superheater and Mechanical Stoker.

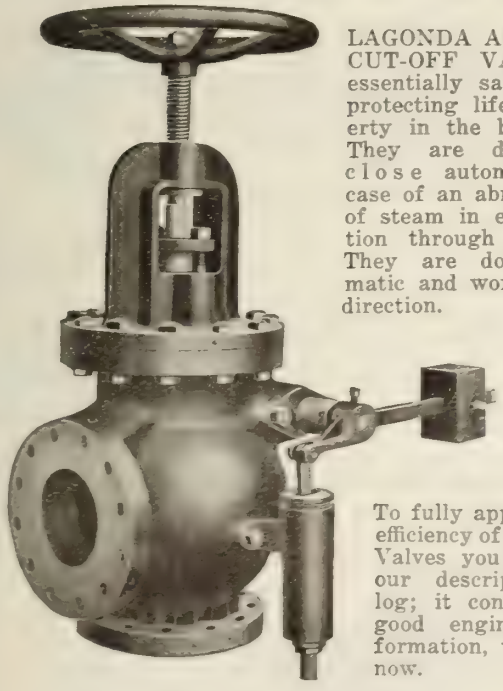
Designed for Rapid, Economical and Safe Production of Steam

Repeated tests are the strongest testimony of the ability of these boilers to raise steam quickly. They withstand sudden and rapid changes of temperature because the parts have great freedom of movement and the boiler as a unit can expand or contract without disturbing the setting.

The average efficiency is ten to fifteen per cent. greater than that of other types, because the water and gases circulate properly with regard to one another and they inter-penetrate each other intimately and thoroughly.

Small parts give excess strength and the boiler is divided into sections so no general explosion can occur. Positive circulation of the water in one direction keeps all parts at nearly uniform temperature. No part of any steam apparatus is made of better material or with more care.

LAGONDA Automatic Cut-Off Valve



LAGONDA AUTOMATIC CUT-OFF VALVES are essentially safety valves, protecting life and property in the boiler room. They are designed to close automatically in case of an abnormal flow of steam in either direction through the valve. They are doubly automatic and work in either direction.

To fully appreciate the efficiency of LAGONDA Valves you must read our descriptive catalog; it contains much good engineering information, write for it now.

LAGONDA
BOILER TUBE CLEANERS

LAGONDA Cleaners are made to be driven by air, steam or water, and in all sizes for straight tubes or curved, in fire tube or water tube boilers. They are sturdily built and can be operated at great speed. Boiler tubes are free from scale where LAGONDA Cleaners are in use.

Superintendent
OR
Chief Engineer

With wide mechanical and electrical experience, best references and connection.

Open for Engagement

Address today to Box 103
POWER HOUSE
143 University Ave., Toronto.

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 100.

FOR SALE—STEAM PLANTS—1. COMPLETE plant consisting of two-72 in. x 16 ft. boilers with tandem compound Corliss Engine, belt, etc., complete. — 2. Plant consisting of 72 in. x 18 ft. boiler with 100 H.P. automatic engine complete. Box No. 27122, Power House. P2H

FOR SALE—45 K.W. Edison D.C. 125 V. Dynamo, 1050 R.P.M., with rheostat and spare armature. In perfect condition and can be seen running up to about end of January. Board of Trade Building, Montreal. Price $250. Apply Superintendent.

CLASSIFIED ADVERTISEMENT SECTION

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

SITUATIONS WANTED

ENGINEER—HOLDING ONTARIO CERTIFICATE, thoroughly experienced in refrigeration and electricity is open for position. Box 17821 Power House, Toronto. P. 4. H.

WANTED—SITUATION AS GAS ENGINEER for producer or city gas, gasoline or kerosene engine. Preferably for small electric light plant, able to do own repairs, climb poles and do own wiring and take full charge. Apply Box 31821, Power House. p.2.h.

EXPERIENCED MACHINIST WITH ENGINeer's certificate, good at general repair work desires position. Apply Box 14921 Power House, P2H

T. H. FENNER'S SPECIAL CORRESPONDence Course for First, Second and Third Grade certificates. Covers all requirements of the Ontario Board of Stationary Engineers. For terms and particulars write T. H. Fenner, Apt. 16, 311 Kendal Avenue, Toronto.

STATIONARY ENGINEER—SECOND CLASS. requires position, ten years' experience of steam generation, refrigeration, cold storage and electric generation, thoroughly experienced with heating systems and hydraulics and all classes of stationary engines, used to large plants, good references. Apply to Box 5122. P.3H.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

Power House advertisers are at your service. Many engineers have been enabled to qualify for better positions, have been instrumental in securing the installation of more efficient equipment, have been of exceptional service to the firm they are engaged by, **because** of their superior knowledge of equipment, which knowledge was largely attained by being conversant with the latest advertised equipment, found in **Power House.**

READ and STUDY the ADVERTISEMENTS

The Safe and Certain Boiler Cleanser

PUT a barrel of BOICO in your boiler room. It's the most efficient and economical **clean-boiler insurance** you can adopt. BOICO routs the most stubborn cases of boiler scale formations quickly and thoroughly.

Hundreds of Plants are Using BOICO Every Day With Unqualified Success

What BOICO will do in one plant it will do in another—**it will do in yours.** BOICO loosens and brings away the hardest of old formations and keeps new scale from gathering. Yet it never does the slightest injury to boilers, valves or packings. Neither does it carry over in the steam, nor cause foaming or priming.

We are confident that BOICO will live up to all our claims and are prepared to let you test it FREE of cost. You have nothing to lose by trying it—let us hear from you.

Anti-Clinker Shell Bar Grates

There's no coal waste where these grates are used. Maximum air-space provides for perfect combustion. No clinker formation here, and you get more heat with less fuel.

One-Piece Jointless Furnace Lining

Why shift the blame on your engineer or fireman when it is your furnaces that are not up to the highest point of efficiency? USE PLIBRICO—it lasts longer than fire brick and is easier to instal.

Tip-It Patent Welding Process

With TIP-IT you get tools with shanks of carbon and tips of high-speed steel.

Dominion Belting Company, Limited

Hamilton, Canada

Sole Manufacturers of the celebrated "MAPLE LEAF" Brand Stitched Cotton Duck Belting and Belt Dressing.

The demand for our products has steadily increased because the standard of quality has been maintained.

We make only one grade, the best that can be produced.

"MAPLE LEAF" is the strongest, truest running, most economical and efficient belt on the market for transmission of power, conveying, etc.

Being thoroughly waterproof it is suitable for running in wet or dry places. **"MAPLE LEAF"** Belt Dressing is different to others offered in that it is equally good for all kinds of belting, leather, rubber, or Balata, as well as our own make.

Write us for prices, and if desired we will be pleased to furnish samples and further information.

A trial order will convince you of their utility.

DOMINION BELTING CO., Ltd., Hamilton, Canada - Quebec Branch: 51 Duluth Bldg., Montreal

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract. Readers are requested to advise the publishers regarding any equipment that they are buying and that is not listed.

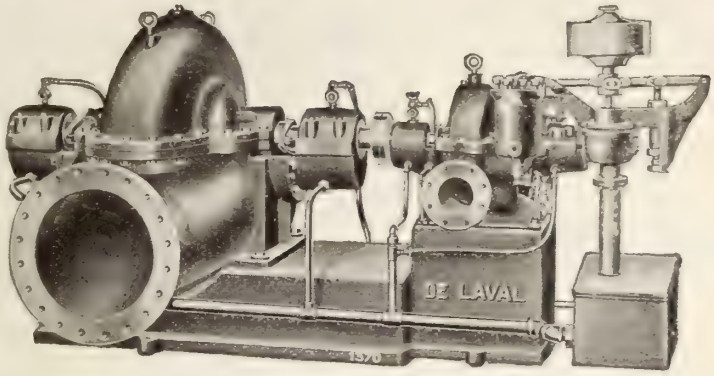
Turbine Driven Blowers
Must Be Rugged

THE DE LAVAL TURBINE-DRIVEN BLOWER unit shown is designed for gas plant work. It serves, however, to illustrate the care taken in designing De Laval apparatus to insure continuous, satisfactory service. Note the heavy construction of all parts, including the blower casing, also the forced lubrication with sight feed and the powerful and accurate speed governor, all features contributing to reliability in operation.

The same features are apparent in the design of all other De Laval apparatus, including turbine-driven generators, centrifugal pumps, blowers and compressors, speed-reducing gears, geared turbines for rope and belt drive, etc.

State class of apparatus in which you are interested and appropriate literature with special data will be supplied. Ask for Catalog F-100.



De Laval velocity-stage turbine driving single stage gas blower 11,000 cu. ft. of free air per min. against 33 in. water column at 3,600 R. P. M.

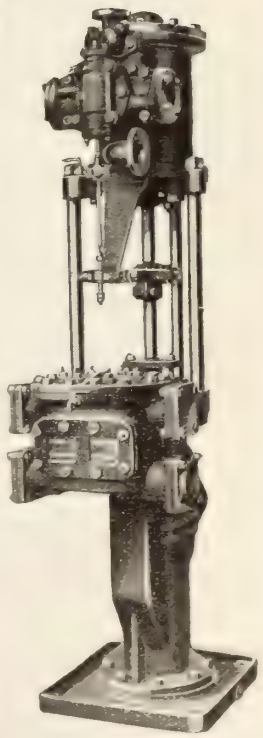
Durability Counts!
HEPBURN
"Special" Ram Pumps

for the highest steam pressures are built on this policy. The Valve Motion parts are of cast steel; the Pump Rod is of bronze and the Piston Rod of steel. The Pump Ram is close-grained cast iron working in a brass sleeve which protects it from damage by dust or ashes. This is a long service pump suitable for the highest temperatures. The "Specials" are operated with Outside Lever Valve Motion.



Get our quotations on Engines, Cranes, Winches, Hoists, Power Presses, Castings and Forgings. Right prices always.

More Power-Less-Fuel

PLIBRICO JOINTLESS FURNACE LINING

in all your boiler settings (front and back arches, baffles, side walls and bridge walls) will **reduce your fuel consumption** by as much as 10%—and thus **lessen your cost of production. PLIBRICO'S** smooth. jointless walls are air-tight and gas-tight, are resistant to heat up to 3,100° F., and last from two to four times as long as the best laid-up fire brick.

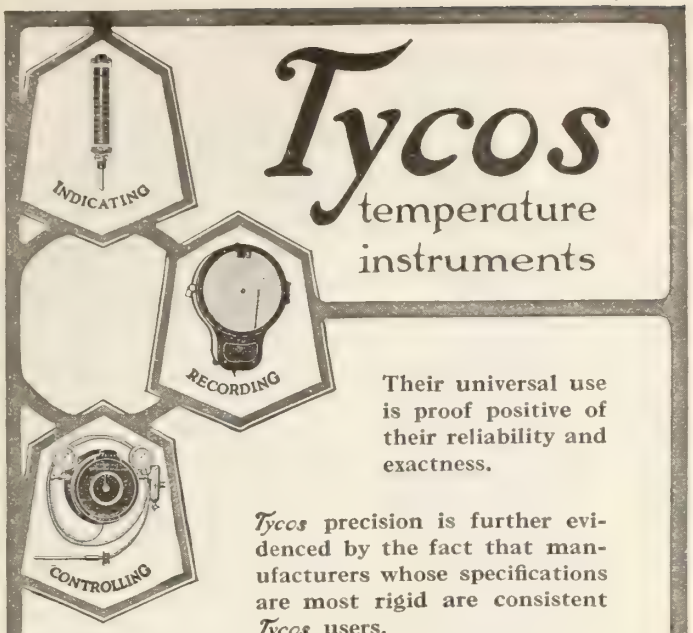
Send for our book, L-30 on "Modern Furnace Building," and learn all about **PLIBRICO,** or ask to have our nearest representative call. **Our service is free.**

PLIBRICO is delivered only in steel containers of distinctive appearance as shown below.

Distributors: Beveridge Supply Co., Ltd., Montreal, Que.; Shell Bar Boico Supply Co., Ltd., Toronto, Ont.; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply & Fuel Co., Winnipeg, Man.; Gorman, Clancey & Grindley, Calgary, Alta.

JOINTLESS FIRE BRICK CO.

1142 CLAY ST., CHICAGO, ILL



Tycos temperature instruments

Their universal use is proof positive of their reliability and exactness.

***Tycos* precision is further evidenced by the fact that manufacturers whose specifications are most rigid are consistent *Tycos* users.**

Place yourself in a position to act quickly when the need arises by sending for catalogues to-day. It incurs no obligation.

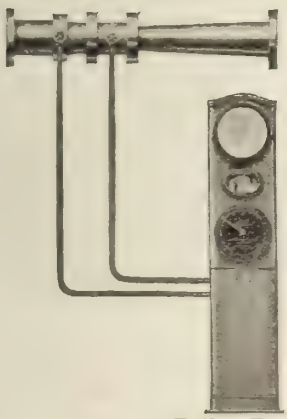
Taylor Instrument Companies

110-112 Church St., Toronto, Ont.

Theres a *Tycos* and *Taylor* temperature instrument for every purpose

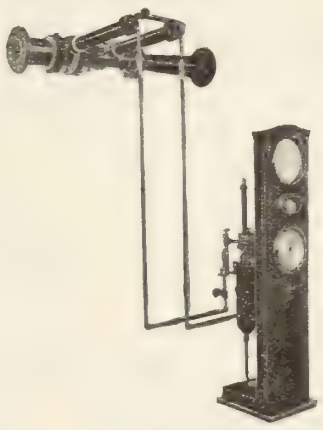
836

THE VENTURI METER WILL TELL YOU



Venturi Boiler Feed Water Meter

1. How many pounds of water are evaporated for each pound of coal burned.
2. Which boilers are efficient and which need cleaning or repairs.
3. When a boiler can be cut out or another boiler should be put in service.
4. Whether or not the water tender is doing his work well.
5. Which kind and grade of coal is most economical for your boiler plant to use.
6. How much steam is used in the engine room.
7. How much steam is used for manufacturing processes.
8. How much steam is supplied for heating.
9. How much condensation is returned to the boilers.
10. How much circulating water is used by the condensers.



Venturi Steam Meter

Is not knowledge of these things vital for efficient power plant operation? The Venturi Meter is giving this information every day in thousands of power plants throughout the United States and Canada. Our accumulated experience in this field is at your disposal. Shall we send you further details?

STEAM DRIVEN **DUPLEX PUMPS** POWER DRIVEN

All parts made to gauge and interchangeable. Give us opportunity to figure on your pumping requirements.

PACKED PISTON BOILER FEED PUMPS

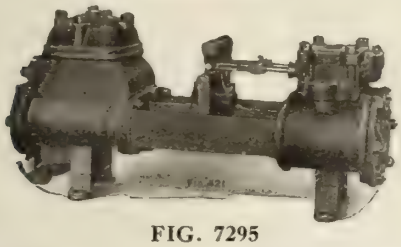

FIG. 7295

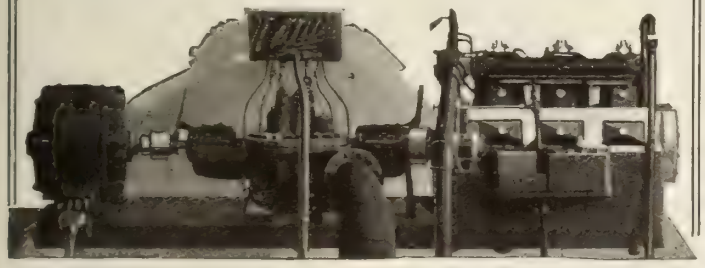
A wide range of steam and power-driven pumps for all conditions of service and for all industrial and public utility purposes.

Established 1852

THE JOHN H. McGOWAN CO.
CINCINNATI, OHIO U.S.A.

Conceded: that no transported power is absolutely certain. **Therefore:** a set like this assures water for fire fighting when, because of storms or mechanical difficulties, power is off.



6-cylinder Sterling engine supplementing electric motor at Lindsay, Ont., on 6″ 2 stage DeLaval pump, installed by Turbine Equipment Co., Toronto. Capacity 1,325 G.P.M. against 290 ft. at 1,450 R.P.M.

The gasoline engine is thrown in with a jaw clutch in case of emergency, such as hydro failure or fire. Costs $20 per H.P. Compare it with any other prime mover.

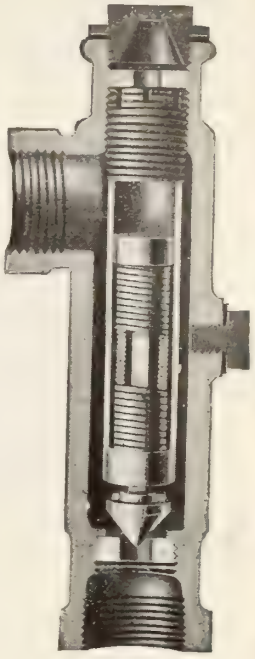
STERLING ENGINE CO.

Dept. C-4

BUFFALO, NEW YORK

12 to 300 H.P. 900 to 1,500 R. P. M.

In-Sufficient Trapping Is also In-Efficient



Not enough trapping is bound to be **inefficient trapping** —bound to result in waste of steam and therefore waste of coal and money.

In many cases, insufficient trapping and the resultant waste and inefficiency seems cheaper than paying the high price of a float or bucket trap, plus their high cost of installation—that's the only reason any up-to-date plant can have for not putting in traps at every point where condensation occurs.

But that reasoning doesn't apply to

STEAM TRAP

SARCO

Although a decided improvement over the old float and bucket traps, Steam Trap Sarco **costs only one-third as much**—and there is practically no installation cost whatever, because there is no building up required, and no platform or other support.

You can buy **three** Sarcos for the price of **one** float or bucket trap—thus, at the same cost, having traps at three points instead of only one. The cost of Sarcos is so small that there is no longer any excuse or justification either for in-sufficient or in-efficient trapping.

Steam Trap Sarco is a Valve, a By-Pass, a Check-Valve and a Steam-Trap all in one, and goes in like an elbow. So small that it can be installed where the big and cumbersome traps would be utterly out of the question. Takes only one-third as much space. Will outlast any old-style trap, and practically never needs adjustment or attention. Will go in the line at any point, at any angle, and without any change in the piping.

Sold on 30 days' free trial. Send for Booklet J-23.

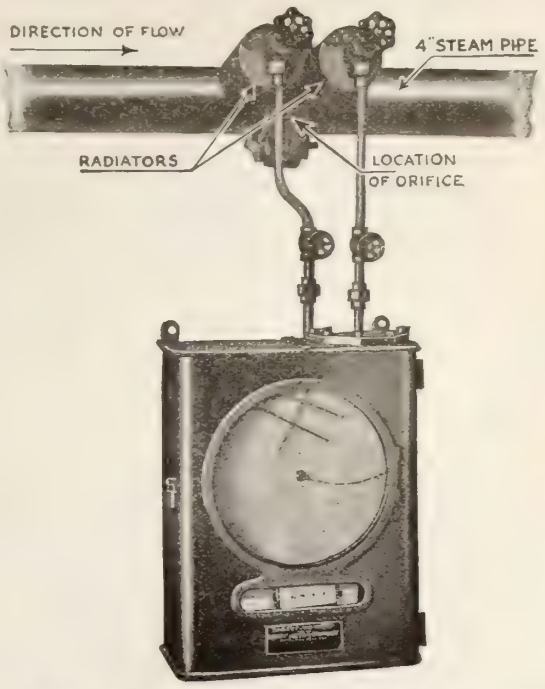
Bailey Fluid Meters

Accurately Record the Steam, Water and Air Flow in Country's Largest Plants



The photograph shows a standard BAILEY Fluid Meter as it is connected for its job of recording and integrating the flow of steam, water or other liquids.

Guessing the steam flow to your turbines, engines and heating systems proves a costly method. Use a BAILEY Meter. It is self-contained, portable, and capacity is made to suit each particular installation. It records rate of flow in any desired units on 12-inch, 24-hour uniformly graduated chart. *Ask for bulletin No. 31.*

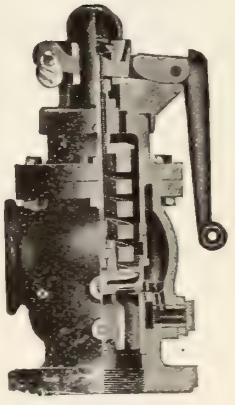
A Point Most Engineers Agree on—

ASHTON

VALVES and GAUGES

top the list!



A record of over forty-five years of leadership endears these specialties to all engineers of experience. They will serve you long and well.

Ashton No. 7 Safety and Relief Valve: This valve for steam and air is a high-class composition pattern in all sizes from ½" to 3" inclusive. Ashton quality and design.

Ashton Pressure and Vacuum Gauge: Hand graduated to insure absolute accuracy. Best material, skilled workmanship and critical inspection insure long dependability.

Above is the **Ashton Pop Safety Valve;** approved by State inspectors and officially adopted by the United States government. Made in all sizes, 2" to 6", inclusive, with many patented improvements. This valve sets the standard for efficiency. These and many other specialties may be obtained from

BUILD YOUR NEXT BOILER FURNACE LINING LIKE THIS

With Betson's Plastic Fire Brick it is easy for anyone, even without experience. No special forms or tools are necessary to lay up a one-piece, jointless furnace lining that is air and gas tight and free from the destructive effects of gases getting back of the fire brick lining, or expansion and contraction. No separate fire brick, tiles or blocks, and no clay mortar joints to give way.

Write for informing pamphlet

50 Carloads of Coal Saved

ELESCO
SUPERHEATERS SAVE FUEL

In a plant operating under a load of 5,000 k.w., 24 hours 2,100 tons or 50 carloads of coal are saved a year by superheating. With coal at $6.00 a ton, Elesco Superheaters would save $12,600.

EVERY 7th DAY A WHOLE CAR LOAD SAVED!

and this represents a saving of only 10%. In smaller plants a higher percentage saving than this is the rule rather than the exception—often a saving of 20% is realized. Elesco Superheaters effect such worth-while savings. In new or existing plants they are applied without changes to boiler settings.

Valuable data is found in our Bulletins T-5 and T-6. Use the attached coupon in sending for them.

TRADE MARK J.M.T. REGISTERED A GUARANTEE OF QUALITY

REDUCING VALVE PERFECTION

J.M.T.

A watchman who spends half his time sleeping is a poor asset to any plant. You wouldn't hire him for five minutes. Can you afford to be less particular of your Pressure Reducing Valves?

The importance of using valves which maintain correct reduced pressure at low maintenance costs cannot be over-estimated.

Morrison Valves are furnished for pressures from 5 to 300 lbs. They are the result of over 50 years' engineering experience.

Morrison Products include Valves for every service, Gauges, Injectors, Ejectors, Whistles, Bells, Steam Traps, etc.

MONTREAL, WINNIPEG, VANCOUVER — LONDON, ENG.: 88 Fleet Street, E.C. — NEW YORK, BOSTON, CHICAGO

Vol. XV.—No. 7 — Publication Office, Toronto—April 5, 1922 — Published Semi-Monthly Canada, $2; U.S. $2.50 a year

Coon Pond Dam showing spillway and intake.

St. Margaret's Bay Power Development

THE Hydro-Electric Power Plants of the N. S. Power Commission are comprised of three separate units.

The Mill Lake Plant has two dams, one 970 feet long with maximum height of 27 feet; the other 380 feet long, with maximum height of 30 feet. The intakes and headgates are housed in concrete gate-houses. Net operating head of this plant, 156 feet.

The Sandy Lake Plant, taking its water from Indian River, will consist of an intake dam at the foot of Sandy Lake; a pipe line 6,000 feet long extending to the power house which will be built as an addition to the one already erected at Mill Lake.

The Tidewater Plant obtains its water partly from Indian River, partly from the Northeast River. Net operating head of this Plant will be 91 feet.

The generating stations at Mill Lake and Tidewater are of concrete, simple and artistic in design.

The engineers have taken advantage of the close contiguity of the two rivers, to utilize a large flow of water with the smallest possible number of generating units; such a layout providing maximum efficiency in hydraulic and electrical equipment by use of large units, with low operating expense and exceptional facility in operation.

The work is under the personal direction of Mr. G. R. Heckle, M.E.I.C., Vice-President of D. G. Loomis & Sons, Montreal, who are the general contractors. Messrs. C. H. and P. H. Mitchell, Toronto, are Consulting Engineers for the N. S. Power Commission. Mr. E. N. Armstrong is Chairman of the Commission and Mr. H. K. Smith, Chief Engineer.

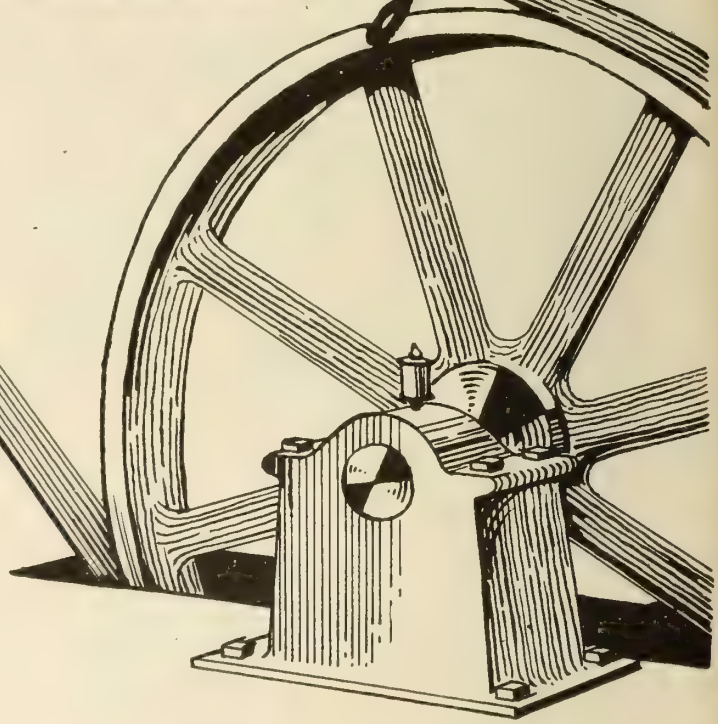
GENUINE OAK TANNED

Leather Belting



Every Length Stamped with the Oak Leaf

Just as the mark "sterling" distinguishes the finest in silver so the Oak Leaf, stamped on every length of D. K. McLaren Belting, indicates true belting economy.

The Oak Leaf means that you have a genuine leather belt. This gives 25% more grip than possible with any other kind of belt. But you have the added assurance of knowing that the leather used is the best obtainable—taken from the **backs** of the choicest steers to be found.

This policy of using the best portion of the best hides has made D. K. McLaren's Belting famous. If you are not a user specify it next time.

We will be glad to give you a list of users as well as full particulars of this belting. Write us to-day.

Every D. K. McLaren belt is **British Oak Tanned.** This is the most efficient method known for producing tough, pliable, stretchless belting. Every belt is guaranteed free from defects of any kind.

Files Hand Stokers Getting Results

PANTHER RUBBER COMPANY, LIMITED

GENERAL OFFICES AND FACTORIES
SHERBROOKE, QUE.

SHERBROOKE, CANADA September 23, 1921.

The Waterous Engine Works Co. Ltd.,
Brantford, Ont.

Gentlemen:

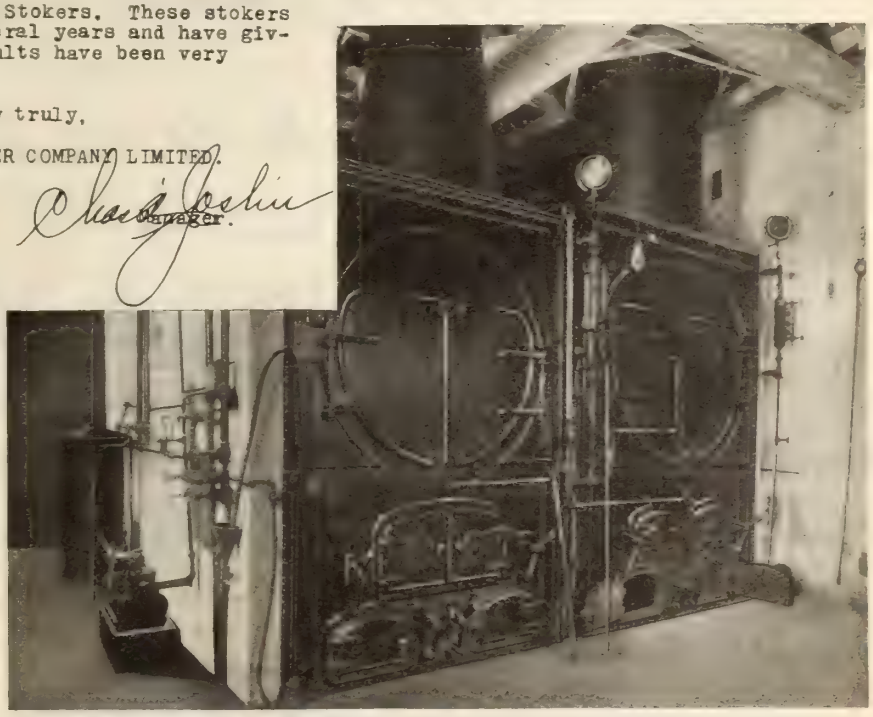
In reply to your letter of the 8th instant we have in our plant the Files Stokers. These stokers have been in operation for several years and have given excellent service. The results have been very satisfactory.

Yours very truly,

PANTHER RUBBER COMPANY LIMITED.

Manager.

CAJ/RMK



It is the uniform excellent service and general satisfaction that have caused progressive men to select **Files Stokers.** These are typical of the more complete data we have compiled:

One installation (3,600 H.P.) saved enough coal to pay for their stoker investment in five months.

A Files installation operated for five months continuously at an average rating of 223%—doubling their steam output.

Files stokers increased efficiency of one plant sufficiently high to warrant discontinuance of two out of eight boilers.

Here is a ready explanation of these achievements:—

1. **Complete volatilization of green coal, causing intensified combustion and smoke dissemination.**
2. **Correct distribution and proper proportion of air according to load carried**
3. **Fuel bed continuously kept clean, uniform and rich.**

Given the opportunity we will be glad to present these facts for your complete satisfaction.

"Everything O.K."

When our Belting Experts make the rounds of the Big Mills and ask if there is anything wrong with the "P.M.S" Belts, the usual answer is "everything O.K." If at any time our customers think "P.M.S" Belts are out of kilter, they are requested to advise us and let us locate the trouble and suggest the remedy. Usually it's the machinery or some unnoticed circumstance. "P.M.S" Belts are wet-proof, dry-proof, heat-proof and cold-proof.

New Truths and Old Fallacies

SPECIFIC GRAVITY

Genuine Babbitt can be left in a molten state indefinitely without causing the ingredients to separate, and permitted to remain at a high temperature without apparent injury. This "fool-proof" quality has endeared it to many babbitt users and fostered its use. It was not known at first, even to the manufacturers of babbitts, that the ingredients of a lead base babbitt would separate if left on the fire for too long a time. In those earlier days of Genuine Babbitt methods, it was a hit or miss proposition in applying Magnolia unless "directions for pouring" were strictly followed.

It is easy to comprehend from the figures below, giving the specific gravity of certain metals, why a Genuine Babbitt does not separate when left in a molten state, because of the slight difference in specific gravities of its ingredients, and why a lead base metal does separate, because of the greater comparative weight of lead, if not occasionally stirred, when in a molten condition.

Metals	Specific Gravity
Tin	7.29
Antimony	6.62
Copper	8.93
Lead	11.35

The specific gravity of a metal represents its weight as compared with the same volume of water.

At one time there was considerable trouble caused from this separation of the ingredients, but now that knowledge is more general concerning it, there is rarely, if ever, complaint from that source.

For

Self-Promotion And Sales Promotion

Are you interested in any of these fields—power—metal working—marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric, Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)

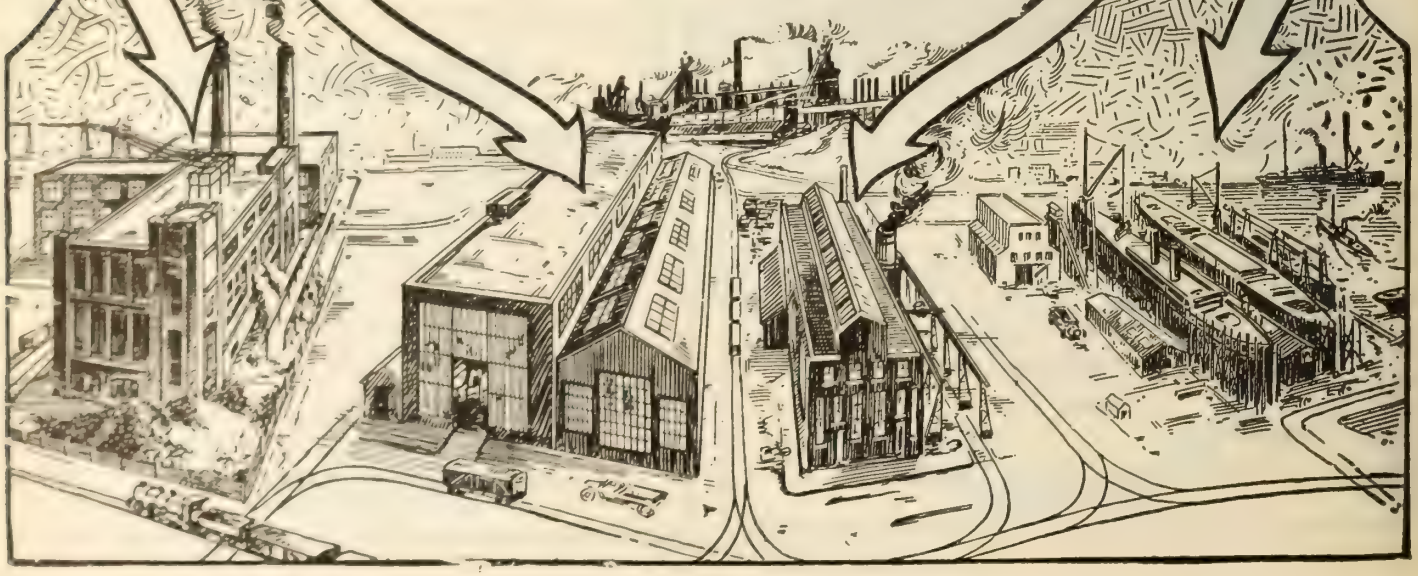
Published by

THE MACLEAN PUBLISHING CO., LIMITED

143-153 UNIVERSITY AVE., TORONTO

A company whose idea of service has made it the largest concern of its kind in the British Empire.
Thirty years' experience and dozens of practical men in your own line, stand ready to serve you. Let them! Subscribe for your paper to-day.

Men with selling problems will find a profitable tip in the statement made by a prominent manufacturer recently, "I use MacLean Publications because I am satisfied that papers with such a high standard of editorial excellence, MUST have an influential following."



Under ideal conditions, with plungers smooth and absolutely in line, the prevention of leakage at stuffing boxes, when handling extremely hot water at high pressures, presents a definite problem.

When plungers are scored and out of line, a packing especially designed for such service will be found in Garlock style No. 443 combination. This packing will prevent leakage and give lasting satisfaction; the rubber cushioned flax and diagonal rings reacting to any lateral movement of the plunger with minimum friction.

Try style No. 443 on your feed pump plungers.

LINDE

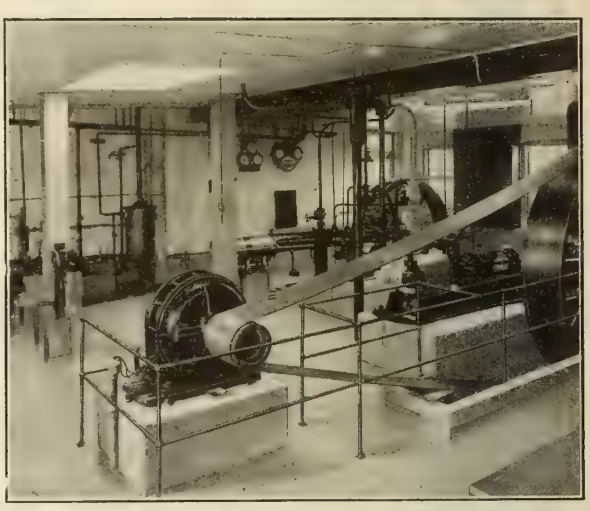
REFRIGERATING AND
ICE MAKING MACHINERY

For Refrigerating and Ice Plants, Large and Small.

Mechanical refrigeration scientifically applied yields increased returns to the user.

Linde Refrigerating and Ice Making Machinery offer every improvement and convenience. Our new vertical enclosed type machines are designed for plants from 1 to 30 tons. Then for demands calling for loads up to 300 tons, our horizontal frame type is guaranteed to give better service than any other equipment on the market.



This 100-ton plant was designed by our engineers These men are at your service. Designs, specifications and estimates upon request.

Thermometer chart from the hardening room of the Chapin-Sacks Corporation, Knoxville, Tenn., December 6, 1921.

What the Thermometer Told

THE overnight record (the upper half) of this chart is of unusual interest. Here are the facts:

Refrigeration was shut off at 6.00 p.m. with the temperature 12 deg. below 0 deg. F. At 11.00 p.m. the temperature was 1 deg. below 0 deg., a rise of eleven degrees due to absorption of refrigeration by the comparatively warm cream.

From 11.00 p.m. to 6.00 a.m. the temperature rose only to 0 degrees—1 degree in seven hours—in spite of the fact that the room was entered once during that period and cream removed.

Such a performance, while gratifying to the owners, is exactly what they expected when they insulated this room with six inches of Nonpareil Corkboard. They knew that the remarkable heat retarding property of Nonpareil Corkboard, by practically excluding outside heat, would fully protect their low temperature and afford the maximum operating economy. They knew also that, being non-absorbent, it would retain its efficiency and not deteriorate. In this, as in hundreds of other plants, Nonpareil Corkboard Insulation has justified the confidence of experienced users of refrigeration.

The importance of adequate insulation for low temperature rooms is fully explained in the 152-page book, "Nonpareil Corkboard Insulation," which you may have free of charge or obligation. Write for a copy.

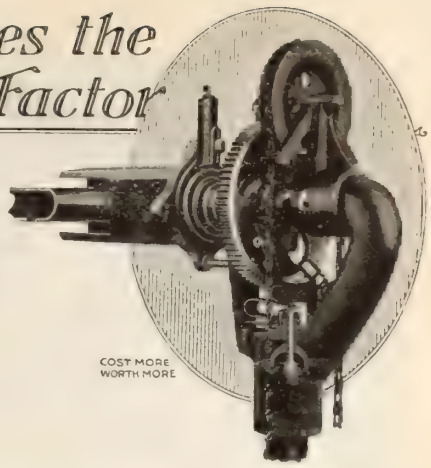
NONPAREIL CORKBOARD INSULATION

For All Cold Storage Rooms

Eliminates the Human Factor



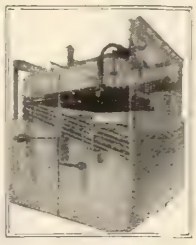
DIAMOND
VALV-IN-HEAD
SOOT BLOWERS

One of the appreciable factors in the efficiency and success of the Diamond Valv-in-Head Blower is that, compared to the independent valve soot blower, the number of manual operations is very greatly reduced and the opportunities for error in those performed are extremely limited. This is due to certain special features of design and construction.

Unit Full Floating—Any possible binding of the blower head, due to movement of the boiler under the forces of expansion and contraction, is prevented by a special mechanism which supports the unit in a spring suspension. As the blower head does not stick and bind there is never any temptation to the operator to pass by certain units in his rounds, or to fail to operate the blowers at scheduled intervals.

Reduction Gear and Ball Thrust Bearings—The reduction gear plays an important part in eliminating the uncertainties of the human factor. Boilers are only effectively cleaned when the steam jets play on the tubes for a pre-determined period of time. With the independent valve soot blower there is no means of controlling this time. The operator may revolve the unit as fast or slow as he pleases. Nine times out of ten he pleases to go too fast, with the result that the cleaning is not as effective as it should be. With the Valv-in-Head Soot Blower the reduction gear so regulates the speed of the blower element, and the ball thrust bearings minimize friction to such an extent, that improper operation is practically impossible, and all tubes are equally and thoroughly cleaned.

Elimination of the human factor is only one of eleven important advantages of Diamond Valv-in-Head Soot Blower. Every boiler needs a mechanical soot blower and you will save money by buying the best.



With the Diamond Valv-in-Head soot blower system, a saving is effected of practically two-thirds in the actual length of pipe required. The elimination of expensive individual control valves in favor of the Valv-in-Head is an important cost consideration. This decreases the initial cost of these items by half or more and reduces radiation losses from the soot blower lines by the same amount.

Diamond Valv-in-Head Soot Blowers are described and illustrated in detail in our new Bulletin 287. Write for your copy.

SOOT BLOWERS - SAVE 4 to 8% FUEL

Long Life is Built Into ABC Vertical Engines

Compact and sturdy—demanding little attention—A B C Vertical Self-Oiling Engines are particularly adaptable for the operation of blowers, generators, pumps and other units.

It is not unusual for A B C Engines to operate continuously for a generation—and scores of engines are performing satisfactorily after having given reliable service for 10, 15 and 20 years.

A B C Engines are economical and will save their original cost in a short time out of the difference in the cost of operation as compared to ordinary horizontal steam engines.

The automatic oiling system reduces the consumption of oil to only about one-fifth of the usual amount.

We will gladly send you complete information regarding A B C Engines and will refer you to plants in your locality where these units have given never-faltering, economical service over a long period of years.

It breaks clinkers' teeth and saves your boiler setting

THE clinker attacks unprotected brick in fire-box walls with a vicious bite. Once it has penetrated, its bull-dog grip can be broken only at the cost of slicing away part of the brick and the mortar between.

But Johns-Manville Heat Treatment gives a clinker no opening for a hold.

The brick edges are not exposed, because No. 26 and No. 31 High Temperature Cements do not fall out from between the bricks. These cements have high tensile strength, and their elasticity allows for expansion and contraction without loosening.

For complete protection an additional over-all coating of No. 32 High Temperature Cement prevents clinkers from clamping on to the face of the brick.

Johns-Manville Heat Treatment strengthens your fire-box walls at their most vulnerable points. In reducing the item of boiler setting renewals and consequent shut-downs, it brings about a welcome economy.

JONES "A-C" STOKERS

It's the cost of stoker *service* that counts---

PLANTS that have installed Jones "A-C" Stokers have found that the most expensive stoker is the hand stoker. Why? Because the cost of hand firing per ton of coal fired is excessive and beyond reason. Yet there is no first cost to hand firing.

Bear this in mind in selecting a mechanical stoker to overcome the exorbitant expense of hand firing. Forget first cost and choose the stoker that costs least per ton of coal fired.

The records of Jones equipped plants prove that there are a number of sound reasons why you buy your stoker service cheaper when you choose the Jones "A-C." It will save MORE coal—by burning a wide range of poor coals with high efficiency. The Jones under-feed principle insures that. It will give greater boiler capacity—by carrying heavy overloads continuously. It will save in maintenance costs, for it is the simplest, most rugged high-duty stoker.

The new "A-C" catalog will convince you that stoker service costs least per year when you operate the Jones "A-C." Where shall we mail your copy?

Refrigeration Talks in Plain Language

The Application of Mechanical Refrigeration to Industry is Getting Wider Every Day. Every Power Plant Engineer Should Endeavour to Understand the Basic Theories—He May Have to Apply Them at Any Time

By T. H. FENNER

OF ALL the aids to comfort which modern civilization enjoys, there are perhaps none that take a higher place than refrigeration. It is used in many widely diversified activities, from the storing of food to the storing of fur coats, and its aid is called in for the production of the films which we see in our favorite picture show. Its use in industry is increasing year by year, and a knowledge of its principles and practice is demanded now from every one who aspires to a responsible position as a stationary engineer.

There is no lack of literature on the subject of refrigeration, and it covers the most advanced as well as the most elementary aspects of the subject. It is a fact, nevertheless, that there are a large number of men who have no knowledge of this most important branch of the stationary engineering profession, and who by their lack of experience, are handicapped in the choice of suitable books on which to begin. It is therefore the purpose of the writer to give a series of articles, of which this is the first, covering the principles and practice of refrigeration in a way to be understandable to the novice, and at the same time, perhaps be of interest to those of more experience.

The Basis of Refrigeration

The stationary engineer, who begins to study, finds out very early in his progress that there is a theory which he must understand and understand very clearly, if he is to grasp the principles of the machine he handles. That is the theory of heat, and in his daily work he is surrounded by evidences of the application of this principle, and has ample opportunity to see the abstract idea in concrete form. Practically the whole theory of heat has been embodied in an axiom or law, which is called the first law of "Thermo Dynamics." Thermo Dynamics is the name given to the laws which govern the application of heat to the generation of mechanical power or movement. The law states "Heat and work are mutually convertible, and every unit of heat, requires for its production, or gives up by its disappearance, 778 foot lbs. of work." Now if we examine these words closely, we find that they mean simply this. Heat and work are two forms of the same thing. If one form appears, the other disappears. If we perform work, we expend energy and create heat. If we expend heat, we get its equivalent in energy, and we can then perform work. Now these are abstract words. Let us look at the units by which we measure these different things, and see how they are related.

The Unit of Heat and Work

Heat itself is a form of motion. It is not a substance, although its effects are substantial enough, and can be both seen and felt through the senses. The first conception of heat by the early scientists was that of an actual fluid, which in some mysterious manner passed in and out of various substances, causing changes of temperature and condition. By long and careful investigation that theory was proved to be a wrong one, and the acceptance of the idea that heat was a form of energy was gradually accepted. Further investigation determined the exact relation of heat to work. These experiments were spread over a number of years, and would occupy too much space to describe them here, but any reader who would like to read a romance might do worse than to get hold of some work on physics which contains the account of the various researches leading up to the final results.

In order to get a clear idea, we will before going any further, define the units of work and heat. Work is the term employed to denote the application of force through a distance, and the unit is a one pound weight lifted through a height of one foot, which is termed one foot pound. One pound lifted two feet high would be two foot pounds. Two pounds lifted one foot high would be two foot pounds. Thus the force on a piston 10 square inches area, and a stroke of one foot, with a steam pressure of 100 lbs. per square inch, would be

$10 \times 100 \times 1 = 1000$ foot pounds.

The unit of heat is that quantity of heat required to raise one pound of water when at its maximum density through one degree on the Fahrenheit scale. The density of water is at a maximum when it is at a temperature of 39.1 degrees Fahrenheit, and above and below that temperature there is a slight change in the quantity of heat required to raise it one degree. We will allude to this again later, when dealing with specific heat.

The quantity of work required to be performed in order to generate the same amount of heat is 778 foot pounds. The unit of heat is called the British Thermal Unit, and the equivalent amount of work is 778 foot pounds.

The time required to raise one pound of water one degree, or the time required to perform 778 foot pounds of work does not affect the quantity. Thus we may take one hour to raise one pound one foot high, and the work would still be one foot pound. We might raise the one pound one foot high by moving it up an inclined plane ten feet in length, but the amount of work performed when we had reached the top would still be only one foot pound.

When we take into account the rate of

doing work we use another unit called the horse power. This is the unit which denotes the doing of 33,000 foot pounds in one minute. Thus if we raise 33,000 pounds through a height of one foot in one minute, we have developed one horse power, while if we take one hour to do the work, we have performed work at the rate of 1 60th of a horse power, or 550 foot pounds per minute. It is important to differentiate between work, and the rate of doing work. We have then three important units. The British Thermal Unit, commonly denoted by the letters B. T. U. and denoting the quantity of heat required to raise one pound of water through one degree Fahrenheit at its maximum density. The unit of work, known as the foot pound, and usually written ft. lb., and the horse power, commonly written h. p., which is the performance of work at the rate of 33,000 ft. lbs. per minute.

Specific Heat

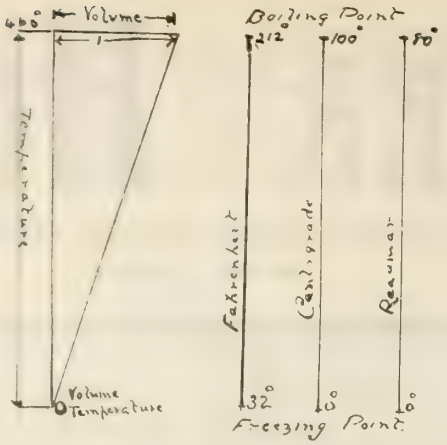
If we denote the amount of heat required to raise water one degree by 1, then the amount of heat to raise any other substance one degree will be a fraction of one, or 1 and a fraction, according to whether the heat required is more or less. For instance, to raise one pound of ice one degree requires only one half a heat unit, so that the specific heat of ice is said to be .5. Thus to raise 10 lbs. of water one degree will require 10 B. T. U., while to raise 10 lbs. of ice 1 degree will only require $10 \times .5$ or 5 B. T. U. The specific heat of water itself is slightly different to 1 when at high temperatures. Thus the quantity of heat required to raise one pound of water one degree when at a temperature of 228 degrees, and a pressure of 20 pounds absolute, is 1.008 B. T. U. as against 1 B. T. U. at its maximum density. From this we get the rule that to find the quantity of heat required to raise any substance one degree, we multiply its weight by its specific heat.

Thermometer Scales

We have spoken of water at 39.1 Fahrenheit, as being at its maximum density. We mention Fahrenheit specifically to distinguish it from the other scales which are in use. There are two thermometer scales which are important to know, and a third which is used very occasionally. They are all different in their divisions, and it is necessary to know how to convert readings from one to the other.

The Fahrenheit scale has its freezing point fixed at 32 degrees, and its boiling point at 212 degrees. There are thus 180 degrees between freezing and boiling point. The freezing point was originally fixed at 32, due to an erroneous idea that 32 degrees below that point was the absolute zero of temperature. This has since been altered, but the scale has been left in its original state.

The Centigrade thermometer is marked 0 at its freezing point, and 100 at its boiling point there being 100 divisions between freezing and boiling points.



Left diagram showing absolute zero of temperature and volume. Right: The different Thermometer scales.

The third scale, known as the Reaumer, is marked 0 at its freezing point and 80 deg. at boiling point, there being thus 80 degrees between the two. We have then three different scales, having 180, 100, and 80 degrees respectively between freezing and boiling point. The proportion they bear to each other is thus

as 180 : 100 : 80

or as

9 : 5 : 4.

That is, the relation that the reading on Fahrenheit bears to the reading on Centigrade is 9 to 5, and to Reaumur 9 to 4. This is not a direct proportion, as a correction has to be made on account of the different position of the freezing point on Fahrenheit as compared to the other two scales.

Suppose the Fahrenheit scale stands at its boiling point 212. We wish to find the corresponding points on Centigrade and Reaumur.

We must first subtract from the Fahrenheit scale the 32 degrees which represents the amount that the freezing point on F. is above zero and then use the proportion. We then have

$$212 - 32 = 180$$

and as the proportion is 9 to 5, Centigrade will be 5/9ths of 180. The expression is

$$(212 - 32) \times \frac{5}{9} = 100$$

If it is Reaumur the proportion is 9 to 4 so we multiply by 4/9

$$(212 - 32) \times \frac{4}{9} = 80$$

It will thus be noted that the procedure is to first subtract the 32 from the Fahrenheit reading before applying the proportion, when the conversion is from Fahrenheit to either of the others. This is important.

In the reverse proceeding, that is converting Centigrade or Reaumur to Fahrenheit, we perform the proportion first and then add the 32.

Thus if the Centigrade thermometer is at 100 the Fahrenheit will be

$$100 \times \frac{9}{5} + 32 = 212$$

while the Reaumur would be

$$80 \times \frac{9}{4} + 32 = 212$$

If it is borne in mind that in converting F. to C. or R. the subtraction of 32 is performed before the multiplication, and in converting to F. from either of the others the multiplication is done first and the addition last.

Absolute Zero

We spoke a little while ago, about the absolute zero of temperature. This is a theoretical conception of a point where neither temperature nor volume exists, and is therefore rightly described as an absolute zero. It is a datum line for making calculations in thermo dynamics, and was determined as follows: It was found that in increasing the temperature of air, a definite increase of its volume occurred for each degree increase of temperature, and this increase was the same at all temperatures. The increase of volume per degree temperature Fahrenheit was found by experiment to be 1/460th, or to be exact 1/459.5. This being the case, assuming that the volume decreased by the same amount for each degree the temperature was decreased, a point would be reached where neither temperature or volume would exist. If the freezing point is taken as a starting point, then at 492 degrees below 32, or 460 degrees below zero Fahrenheit we should come to the absolute zero. Absolute temperature is denoted in formulas by the capital T.

On the Centigrade scale the absolute zero is of course different, by reason of the different divisions. The increase of volume per degree Centigrade is 1/273-rd, and thus we find the absolute zero would be at 273 degrees below zero Centigrade. These are the two quantities used in all calculation on volumes of gases.

Latent and Sensible Heat

Heat is not always presented in a form that can be seen or felt, although its effects may be quite apparent, as is the case with the electric current. Heat which causes an alteration in the reading of a thermometer scale, or can be felt by the body, making itself apparent to the senses is called sensible heat. The reason is obvious. A considerable quantity of heat may be absorbed without any difference being apparent on the thermometer, the effect being noticeable by a change of state in the body absorbing the heat. This kind of heat is therefore called latent heat. Latent heat is a most important factor in the application of heat to the development of power, in an engine, and is equally as important in the application of the principles of heat to the production of cold. It may sound

peculiar to the beginner when we state that we need to produce cold, but we will be able shortly to make this seeming paradox quite understandable to him.

In order for water to be turned into steam, or ice to be turned into water, a certain amount of heat must be absorbed, which will have no effect on the temperature of the water or ice. In order to condense steam into water, or to change water into ice, a corresponding amount of heat will be given up to surrounding atmosphere or other medium, without any effect being noticed on the thermometer. This heat is the latent heat. If we take a piece of ice weighing one pound, at a temperature of 32 degrees, and wish to obtain one pound of water at 32 degrees, we must apply heat to make the change. This quantity of heat would be absorbed by the ice, and would be present in the water, but the temperature before melting and the temperature after melting would be identical, 32 degrees. We know from experiments and research just what this amount of heat will be, and in the case of ice it is 144 B. T. U. In the same way to turn one pound of water at atmospheric pressure into steam at the same pressure the amount of latent heat required is 966.6 B. T. U., which is absorbed by the water, and is present in the steam, in addition to the quantity of heat added to bring the water from 32 degrees to 212, which is 180 B. T. U.

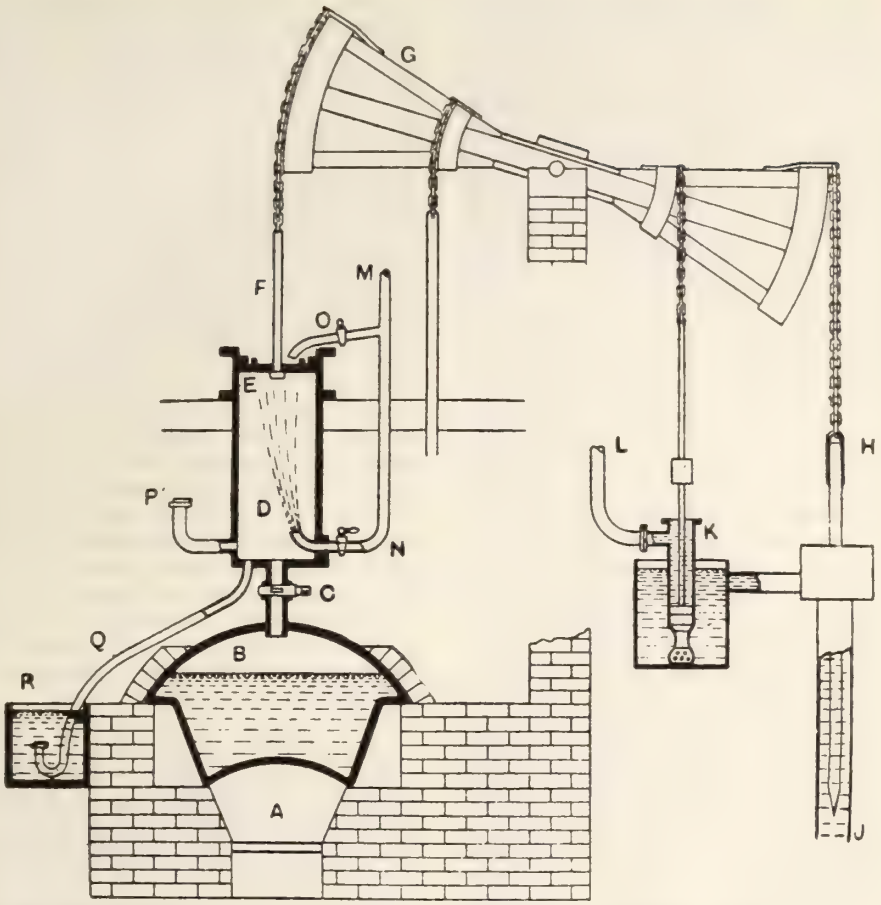
The total heat of steam is then the sum of the latent heat and sensible heat and the total amount of energy available in the steam is the product of the total heat by its work equivalent, or B. T. U.'s x 778. Now if we wish to condense this steam back to water at 212 degrees, we have to use some means to carry away the latent heat. Now in order to transfer heat from one body to another, the body which is going to take up the heat must be at a lower temperature than the body which is going to give up the heat, as the transfer of heat always occurs from a hot body to a cooler one, and cannot possibly take place in the other direction. In order to condense the steam then we usually use water at a much lower temperature than the steam, and raise the temperature of the water. Thus if we have available water at a temperature of 60 degrees, and wish to condense our pound of steam we shall have to use a quantity of water depending on the amount the temperature of the water is to be raised. Suppose we are going to have an increase of 20 degrees in the temperature of the water, that is 20 B. T. U. per pound of water used. As we have 966.6 B. T. U. to carry away, we shall need 966.6/20 or 48.3 lbs. of water required to remove the latent heat from the steam and change it back to water again.

Radiation, Conduction, and Convection

Having obtained a fundamental idea of the nature of heat, we can now enquire into the manner in which this heat is transferred from one body to another. There are three distinct ways in which this heat transference takes place, first by radiation, second by conduction, and third by convection. A hot body radiates heat in straight lines through the atmosphere, part of it being absorbed on the way, its intensity varying with the square of the distance from the radiating body. Suppose we have a hot body in the centre of a space. The intensity of the heat at a distance of one foot may be taken as 1. Then at a distance of two feet it will be divided by the square of 2, at four feet divided by the square of 4. That is at 2 feet the intensity will be ¼, and at 4 feet 1/16th of the intensity at 1 foot.

The heat from the burning coal in a boiler furnace is radiated to the heating surface of the boiler. It passes through the plate by conduction. Different metals have different powers of conduction. Copper is among the best, while lead is one of the worst. Taking silver as 100, copper has a conductivity of 74 and lead 8.5. Iron and steel are about the same, 11.9 and 11.6 respectively. Water is a very bad conductor of heat, but is a good conveyor. Convection of heat is literally the carrying of heat from one place to another by a current, such as a current of water or a current of air. The water in a boiler is heated by convection, after the heat has been conducted through the plates to the water. The water immediately in contact with the heated plate becomes lighter with the increase in temperature, and rises, cooler water taking its place, and in turn becoming heated and rising. The heat is thus gradually carried all through the water in the boiler by convection.

Heat is again lost by conduction through the plates of the boiler to the surrounding air, and radiated away. Hence the necessity of good insulation.



A The boiler furnace.
B The steam boiler.
C The steam valve.
D The engine cylinder.
E The piston.
F The piston rod.
G The main beam.
H The heavy pump rod.
J The mine pump.
K The pump for condensing water.
L Condenser pipe.
M Condensing water pipe.
N Injection cock to cylinder.
O Water tap on top of piston.
P Relief valve.
Q Eduction pipe with non return valve.
R Feed water tank.

Application of Heat to Work

We know that heat is interchangeable with work, but we have not yet seen how this interchange can take place. We said that in the case of the pound of water changed into steam, that it contained after the change the latent heat necessary to make the change, and the sensible heat which raised the temperature from the melting point of ice to the boiling point of water. The melting point of ice, is always taken as the basis for the calculation of the quantity of heat available. We have then in one

pound of water at atmospheric pressure 212—32, plus 966.6 heat units. That is 1,146.6 B. T. U. and this is equivalent to 892,054.8 ft. lbs. Now if we could use all this energy contained in that pound of steam in one minute, we should have 27 horse power. Unfortunately we cannot do this, and the amount that we can use is a very small fraction of the total. In fact the only way in which we could usefully employ this steam to develop power would be to deliver it to the blades of a turbine which was operating under very low back pressure, that is a pressure considerably below that of the atmosphere. We could use it very well for heating. In order for it to perform work, we must have different conditions. The first application of the heat in steam to developing power in an engine was Newcomen's pumping engine, and a brief description of its action here will be of service to the reader. Later on he will see a certain likeness between the processes in a refrigerating machine and those in Newcomen's engine. The illustration shows the general arrangement of the apparatus.

Suppose the piston at the top of its stroke, and the under side filled with steam at atmospheric pressure, which was all that was carried on this engine. There is then atmospheric pressure on top of the piston, and also underneath it, maintaining a state of equilibrium. The heavy pump rod and pump are at the bottom of their stroke. At this point a jet of water is introduced from the tank to the cylinder, condensing the steam therein. Now steam at atmospheric pressure occupies about 1,600 times the volume of the water it is formed from, and conversely the water will only occupy 1/1600th approximately of the space occupied by the steam. The result of the steam under this piston being condensed is then to lower the pressure considerably below that of the atmosphere, or in other words, to form a partial vacuum. The equilibrium of the piston no longer exists, and the pressure of the atmosphere forces the piston down, pulling the pump rod up. In order that the pump rod may again descend, it is necessary to again equalize the pressure on each side of the piston, which is done by opening the valve between boiler and cylinder and again filling the cylinder with steam at atmospheric pressure. The weight of the pump rod then over-balances the weight of the piston and beam, and the piston goes to the top of the cylinder, the pump descending to the bottom of its stroke.

Although at first it may be hard to see just how the heat in the steam performs work in this case, yet a little examination will make it clear. The work done by the atmosphere on the piston is equal to the difference in weight between the piston, rod, and half the beam, and the weight of the pump rod, pump, and half the beam, plus the weight of the water multiplied by the height lifted. Now we have obtained this work by creating a difference of pressure between the two sides of the piston, and in order to obtain that difference of pressure we have been compelled to dissipate the heat. In this case, we have given it up to the water from the condenser tank, which is injected into the space under the piston. Now if instead of utilizing the difference in volume between steam and its condensate, we might have achieved the same object by exhausting the air from under the piston by means of a pump, we should have had to apply power to the piston of the pump in some form, and the work done would be equal to the mean effective pressure against which the air pump worked by the displacement of the piston while emptying the cylinder of the engine. This work would be the equivalent of the power applied to the pump, and this power would have a definite heat equivalent. In the Newcomen engine, the heat applied to the water in the boiler appears in the steam, and is then given up to the water injected into the cylinder, changing the steam back into water.

Heat is Not Lost

It will be noticed that in all these operations, the heat appears in one form or another, but at any stage of the cycle, there is always the same amount of heat present. We take a certain amount of coal and place it on the grate of a boiler. We say that it has a certain heat value. We mean by this that in the disassociation of its various constituents during the process of rapid combustion, in conjunction with the oxygen of the air, heat will be evolved. This heat is the equivalent of the heat that has been absorbed by the coal through long centuries of change from the original tree. The heat given up by the coal reappears in the water in the boiler, though not all of it. Some has gone to heat the brick setting, and radiated off to the atmosphere, but if we had sufficiently delicate instruments we would find that the increase of temperature in the boiler metal, the water, the setting, and the atmosphere surrounding it would just be equal to the heat given up by the combustion of the coal. We carry the heat in the form of steam from the boiler to the engine, where some more heat is given up to the surroundings on the way. The steam is applied to the piston of an engine, driving it forward, and in doing so giving up heat. The exact equivalent of this heat is present in the form of work which has been done on the piston, and in overcoming the friction of bearings. We still have a considerable amount of heat in the steam, when the piston has reached the end of its stroke, and in many cases this steam is ejected to the atmosphere. By just the amount of heat remaining in the steam the atmosphere will be raised in temperature, but owing to the tiny quantity of steam compared to illimitable amount of atmosphere this cannot be noticed. This increase of heat in the atmosphere at the expense of the steam causes it to change its state from a vapor back to its original state of water, at atmospheric temperature, which is what we started from. In all these operations there has been nothing lost and nothing gained. The original heat energy of the coal has been changed into different forms, and a certain proportion of it into useful work, but nothing has disappeared.

This is briefly the theory of the conservation of energy, which means that there is a certain amount of energy available in the world, and that this energy is the same today as in the beginning, and always will be. It is never destroyed, it merely changes its form. It cannot be created. We can change heat into work, or generate heat by the performance of work, but we cannot create either. By changing one into the other we can during the process apply a certain amount of the heat to useful work, but we can never get the exact equivalent of the heat in the form of work. A certain amount is lost in overcoming friction, either mechanical or chemical, and although we can bring this down to very fine limits, we can never hope to eliminate it.

This is expressed in the second law of thermo dynamics, which is stated in various ways. We will give two of them here. First "No change in a system of bodies that takes place of itself can increase the available energy of a system."

The second is Lord Kelvin's definition, "It is impossible by means of inanimate material agency to derive mechanical effect from any portion of matter by cooling it below the temperature of surrounding objects."

These fundamental laws are necessary to the understanding of the student of refrigeration, and he can by their aid grasp the idea of the principles without any deep excursion into the realms of higher mathematics. He must understand clearly the relation between heat and work, and also another point that seems to be a stumbling block to many men, that is the relation between heat and temperature. A piece of ice though cold to the touch possesses heat. It has a certain amount of heat at a low temperature. You may have 1000 B. T. U. present in a body at a temperature of 1 degree, while in another body you may have the same number of B. T. U. present at a temperature of 500 degrees. The same amount of heat would be present in each, but there would be a difference of 499 degrees in their temperature. Probably a good comparison of this would be in the case of the weight and pressure of steam. If you have one pound of steam at atmospheric pressure in one case, and the same weight of steam at 100 lbs. pressure in the second case, you have the same weight of steam in both, but only 1/100 the volume in

Continued on page 29

Steam Flow Meters

By E. KIEFT

Engineer of Tests, Gary Works, Illinois Steel Co., in "Combustion."

IT IS with the steam flow meter as it is with the world in general. The world is neither good nor bad; it is what we make of it.

The steam flow meter is one of the most valuable instruments in any power plant and in any manufacturing plant where steam is used to any considerable extent, i. e., the steam flow meter ought to be used on any plant where the production or consumption exceeds 15,000 lbs. of steam per hour. In many smaller plants where steam is widely distributed, it would be a profitable investment to use a steam flow meter of a suitable type for the purpose. There are conditions where a portable steam flow meter will give very satisfactory results and there are also cases where it would be advisable to have a central steam flow meter installed connected electrically with the different steam consumers or producers.

There exist various opinions about the reliability and accuracy of a steam flow meter. It is my experience that a steam flow meter will do the work that it is proposed to do, if those in charge of the installation and operation follow the builder's instructions, using, besides, a little common sense in selecting the proper location for the apparatus.

The principle on which the steam flow meters work is generally a function dependent on the laws of gravity. What is more reliable than gravity? For operation most steam flow meters depend upon the differential pressure obtained by means of pitot tubes, venturi tubes, nozzle tubes or orifice plates. The latter are the most convenient for the purpose, but great care must be taken when making the pipe connections. The most important point to observe is that the meter taps are at the proper distance from the orifice plate; further, the connections leading to the meter body must be absolutely tight, otherwise there is a possible error due to faulty differential indications. All the other devices for getting a differential pressure will give satisfactory results when applied in the proper manner.

Any kind of differential pressure can be obtained for a given quantity of steam by varying the size of the pipe when using pitot tubes or nozzle tubes. The size of a venturi throat governs the differential pressure obtainable with a venturi tube and the size of the orifice of an orifice plate gives also any desirable differential. In most cases we can make a rough estimate of the possible variation of the quantity of steam to be measured so that it is required of the engineer in charge to get a practicable differential pressure suitable for the type of meter he wants to install. Anyone who wishes to install a steam flow meter can get all the necessary information from any of the leading flow meter manufacturers.

There are corrections to be made for the density due to fluctuation of steam pressure, moisture or superheat. These corrections are only necessary for specific conditions such as in boiler tests and scientific investigation work. An average meter factor will answer all general operation requirements.

Statements of some critics that steam flow meters do not help to carry the boiler load are ridiculous. They might as well state that a compass or sextant will not move the ship or that the steam flow meter has not any calorific power. Arguments about the incompetency of firemen and ignorance about the functions of a stack damper are poor excuses which reflect more on the ability of the boiler foreman or power plant engineer than on the steam flow meter.

A standard boiler test code does not recognize the flow meter as a suitable means of measuring the performance of a boiler when efficiency is to be determined, due to the fact that this code has to be a general code, suitable for any engineer in detail, and for any layman in general, in order to suit engineering and commercial requiremets. To my knowledge boiler tests have been made with venturi water meters and steam flow meters. Among these were so-called acceptance tests, giving me just as much confidence in my results as other tests which were made in compliance with the standard test code, i. e., weighing the water. One instance is known of a boiler being credited with about 25 per cent. more steam than it actually made, notwithstanding the fact that the water was weighed. When the water is weighed someone is always needed to put the figures on paper. The mental factor of the man who records, is just as liable to go out of commission as anything else. There are all kinds of leaks occurring for which you can not blame the boiler.

What is the use of an engineering education if we do not apply the theories in practice? If a big concern like the General Electric Company with a world-wide reputation is putting something on the market, you may be confident that it is something more than a mere plaything. The same thing can be said of the other leading flow meter concerns. They all have engineers of high standing.

The leading steel manufacturing plants are generating vast quantities of steam by utilizing waste heat from the open hearth furnaces, surplus blast furnace gas, coke oven gas, coke breeze and all kinds of inferior fuel not suitable for steel manufacture. There are even times that they have a surplus of waste heat and inferior fuel. Steam flow meters have been used in these plants for the past ten years and in many of them there is an increased demand. Even during the prevailing depression times there are some funds allowed for the installation of steam flow meter equipment; this is the most convincing explanation and answer for the question: "Is a steam flow meter a paying investment?" Steel mill executives do not spend money for ornamental equipment —they go by the cost sheets. If a steam flow meter is already a paying investment at a steel mill, how much more will that mean for a plant being dependent on coal only for fulfillment of the steam requirements.

Concerning the financial saving when using steam flow meters, it may be stated that a minimum saving of 5 per cent. in operating cost can be obtained on any plant of more than 15,000 lbs. capacity (this does not include plants that are already equipped with other kinds of scientific instruments such as CO_2 recorders, automatic draft regulators, etc.); further, that at many existing plants there is a possibility of a 10 per cent. or greater saving by installing a steam flow meter. It is understood that the steam flow meter is in the hands of a man who can interpret results; further, that the draft gauge is part of the boiler installation and that the damper of the boiler is not entirely out of commission. The steam flow meter shows you what your conditions are if you apply the results with a little common sense. If you have an installation, let us say of twenty boilers to equip with steam flow meters, the first question is how to get a maximum amount of information with a minimum amount of equipment. This question is answered according to my experience by putting a central steam flow meter in the office of the boiler foreman, if he has any, or otherwise select a spot just as good and connect this central meter electrically with each boiler. Steam flow meter equipments similar to the kind put on the market by the Republic Flow Meter Co. will be very suitable for the purpose. If the money is available, then there is also a justification for a simple indicator on each boiler, provided that this does not involve considerable piping and pipe-fitting. The length of pipe connection between the taps at the unit inserted into the steam line, and the unit which converts the velocity into a differential pressure must be a minimum in order to reduce trouble.

What does the steam flow meter then show?

First: It tells which boilers are out of step or loafing on the line.

Second: It makes you go out on the firing line and look for the little things, such as leaks, settings, improper air distribution under the stokers or grates, the effects of forgetting to keep the soot from the outside of the boiler flues, and the physical meaning of a stack damper.

Third: It will increase the inventive

spirit of the organization of the boiler house—everyone gets more enthusiastic about the performance. That is at least my experience. There are many operators and engineers who have never taken notice of the importance of feeding the boiler in a systematic way. To keep the water always on the same level appears e the best way, but if you hunt up your books and papers on Thermodynamics and sit down, doing a little figuring and sound reasoning, you will find that a boiler can also be used as a steam accumulator by bringing the water up high in the glass during the light load and allow the water to go down to the bottom of the glass during the peak loads. You will find that there exist certain connections which permit of the sudden inrush of feed water, as some automatic regulators permit when the load comes on, and are thus more responsible for sudden drops in pressure than the peak load proper. Right there is something for the progressive operator or engineer to look into.

Fourth: In case of waste heat installations, you may find that your boiler does mighty well on a certain day. You feel proud about that boiler, and go out in the field to study the special features of this boiler and its environment. Gas analysis, temperatures, and pressures are taken all the way from the open hearth or any other furnace to the stack, and before you are through you have found from your analysis that vast quantities of the principal fuel are bypassing through a leaky valve. One discovery of this kind pays for the whole installation. Some other day you find the steam flow meter on some other boiler reading quite low. Again you go out exploring and you may find waste gases, air and water at their afternoon party, meeting in the flues before they enter the boiler, causing low entering temperatures and consequently low steam output. Somebody may ask: "Can you not find out these things without a steam flow meter?" Certainly you can, but the steam flow meter is a great help. The above statements are not stories—they are a few of the many facts observed during years of personal experience with steam power, electric power and many branches of metallurgical engineering.

HORSE POWER CHART

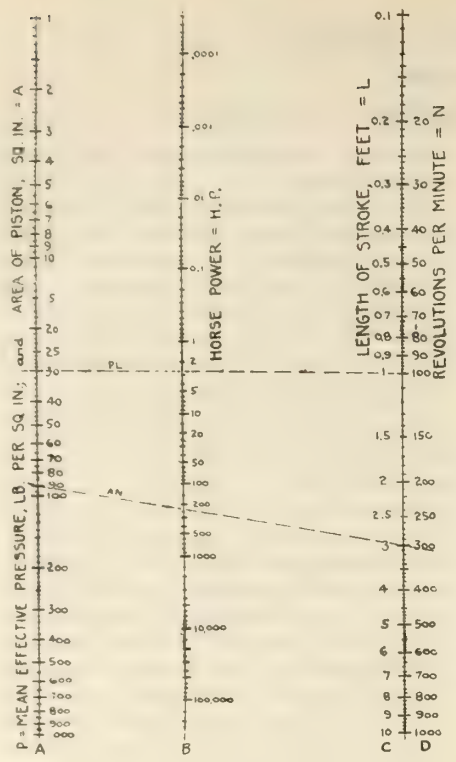
By W. F. Schaphorst

This solves the much-used formula

$$\text{Horse Power} = \frac{\text{PLAN}}{33{,}000}$$

For example, what is the horse power of the crank end of a steam engine, the mean effective pressure being 30 pounds per sq. in.; the piston area being 90 square inches; the length of strokes one foot; and the number of revolutions being 300 per minute?

Connect the 30 (Column A) with the



1 (Column C) and locate the intersection with Column B. Then connect the 90 (Column A) with the 300 (Column D) and locate the second intersection with Column B. Now locate the mid-point between the intersections in Column B. It is a simple matter to find the mid-point by folding a piece of marked paper, by means of a pair of dividers, by measuring with a rule, or any other easy way of bisecting a line.

The mid-point, Column B, gives the horse power of the crank end as being very close to 25 h.p. Multiply it out "longhand" and you will find the exact power as given by the formula to be 24.5 h. p.

The chart will therefore prove itself to be highly useful in checking over your figures, in case you are desirous of being absolutely sure of your computations. Generally, it will be found close enough for most practical purposes.

It will be noted that the range of the chart is very great indeed—running up to over 100,000 h. p.—thus including every steam engine ever built. The lowest range is 1/10,000 of a h.p., which would be a most delicate toy engine.

A USEFUL EXPANSION CHART

By N. G. Near

Machinists will find this chart useful for determining the expansion to be allowed in piping rods, tubes, etc., for various temperature differences without doing any "longhand figuring" whatsoever.

To use the chart simply lay a straightedge across it once, or stretch a fine black thread across it, as indicated by the dotted line, and the problem is solved without further ado.

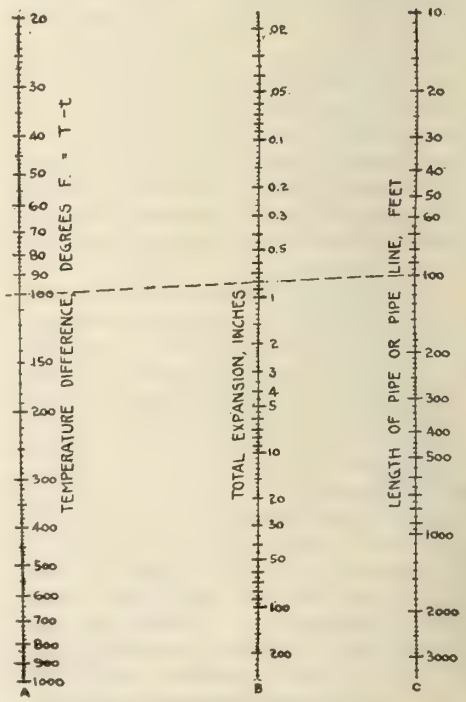
For example, a certain pipe line is installed which is 100 ft. long. It will be subjected to a temperature variation of 100 degrees F. What will be the total expansion in inches?

Connect the 100 degrees temperature difference, Column A, with the 100 ft. length, Column C. The intersection with Column B gives the answer as 0.8 inch. That's all there is to it. Very simple indeed.

Inversely the chart can be used for determining the allowable temperature difference where a definite amount of space is available for expansion and contraction. Thus if the length of the pipe line is 100 ft. and the allowable expansion is 0.8 inch the same line would show that a temperature difference of 100 degrees F. would be the limiting amount.

Also, if the factors in Columns A and B are known, the unknown in Column C is immediately found. In other words, if any two of the factors are known the third factor is very quickly found, and without any computing whatever.

It will be noted that the range of the chart is wide enough to take care of almost any expansion or contraction problem that the machinist may have to contend with. The temperature difference, Column A, varies all the way from 20 degrees to 1000 degrees. It is very seldom, if ever, that we have as high an amount as 1000 degrees. The length of pipe line, also, is great, varying all the way from 10 ft. to 3000 ft., or more than a half of a mile. And the total expansion between these limits varies all the way from 0.02 inch to 200 inches. It is interesting to note that if we had a pipe line 3000 ft. long, with a temperature difference of 1000 degrees, the expansion would be over 200 inches.



Generating Steam By Electricity

Under Certain Conditions it is Possible to Use Electric Power for Steam Generation Purposes. It is Being Done in Some Canadian Plants To-day, and Has Been Used in Europe for Some Years

WHILE there has been in European countries, a considerable use of electric steam generators, the principle has not been very widely used in Canada, or the United States. There are some installations that have been operating for a short time in this country, and these installations together with a description of the general principle were described by Mr. F. T. Kaelin, Chief Engineer of the Shawinigan Water & Power Co., at a recent meeting of the Engineering Institute of Canada.

Advantages

Under prevailing conditions where electric power is sold on a kilowatt hour basis, electric steam generation cannot compete with steam produced by fuel, but it is not beyond the possibility that in some remote places where the cost of fuel and freight are high and the cost of a hydro electric development is low, the electric steam generator with its very low capital investment and operating expenses may become a competitor to the method of generating steam by burning coal or oil, but it is not necessary to consider such an exceptional case to prove that the generator fills well its place permanently as a transformer of idle power into useful heat energy. We may consider its usefulness mainly from two different points of view:

Consumers

1. From the point of view of the consumer of electric power owning a hydro electric installation, or purchasing blocks of firm hydro electric power on a flat rate power contract and using this power for manufacturing purposes only, during a smaller part of the twenty-four hours. In many manufacturing plants steam has to be produced for cooking processes, drying, humidifying, and in all cases heat is required for heating purposes during six months and during the full twenty-four hours. Here we have electric power lying for twenty-four hours and paid for. The thought comes to us, what can be done with this idle power? Is there any cheap way of transforming this electric power into something useful? It is well known that electric energy can be transformed into heat energy at a very high efficiency. One of the cheapest ways of doing this is to produce steam which in most cases can be used in conjunction with other steam generating apparatus, and where a system of piping for the purpose of heating or using steam for manufacturing purposes already exists.

The low cost of the steam generator compared with other electrical apparatus for the conversion of electric energy into heat, and the wiring and control apparatus necessary for such equipment, is very much in favor of the steam generator. It can be shown that even in extreme cases where the load factor is comparatively high, for instance in pulp and paper manufacturing plants using a considerable amount of power during six days of the week and having it idle for the seventh day and at the prevailing cost of hydro electric power purchased in big blocks by these companies that it is economically quite feasible to turn the power which was used during six days, mainly for pulp grinding, during the seventh day into steam which is always required in such places, either for manufacturing or heating purposes. It was shown in an investigation made lately that the saving of coal during the fifty-two Sundays and three holidays would easily pay for the installation of the steam generator in less than one year, and there are no doubt quite a number of pulp and paper plants in this country where similar conditions exist and where a considerable saving could be accomplished.

Power Producing Companies

2. From the point of view of the Power Company producing and selling hydro electric power, the present commercial depression and slowing up of the industrial activities have left hydro electric companies with surplus of power for disposal. How long this condition is going to last is uncertain but there is no doubt that a considerable amount of unused power will be available for the next two or three years. Power companies can afford to sell this power at cheaper rates during such time as there is no other market for the power, though preferably under conditions which allow the power company to cancel the contracts on short notice. But at the same time it must be clearly understood that no power company could afford to develop hydro electric power for the main purpose of generating steam electrically in competition with coal.

The problem has been to find a use for this idle power which would not require any expensive installation, new machinery or additional apparatus, for instance, transformers, etc., and as it was out of the question to use the power, for new industries or the manufacture of new products which require considerable power like those produced in the electro-chemical industry, one of the solutions was to turn the electric power into heat in the form of steam which is used to a very great extent in many industries, especially in the pulp and paper industry. To do this, of course, other factors have to be favorable such as the transmission of the power, the proper voltage available that would not mean any further transformation and the low cost of the whole installation for generating steam electrically.

Although some of these installations which are in operation to-day may be considered as quite temporary due to the prevailing exceptional conditions, there is no doubt that in many cases the electric steam generator is going to stay and be used at such times as there is power available from the power companies. This is usually the case during three or four summer months when the water-flow in the river is high and a certain amount of surplus power is available. It may even be feasible to use only night power by close co-operation of the power company with the power user, and the fact that starting and stopping electric steam generators takes only a few minutes. These are all points which make the steam generator a very flexible apparatus and make it very useful to convert electric energy at any time at short notice and at extremely low cost to valuable heat energy.

Efficiency

In the electric steam generator all electric energy is converted into heat energy, the electric current passes through a resistance either of metal or formed by the water to be evaporated. The whole process of conversion is therefore governed by ohmic law. 1 k. w. h. is equivalent to 3,412 B. t. u., the total heat content of 1 lb. of steam at an absolute pressure of 150 lbs. per square inch is 1,139 B. t. u. Assuming feed water temperature of 150° F. the total heat to be supplied will be 1.139—(150-32) = 1,075 B. t. u. 1 K. W. H. will therefore produce

$$\frac{3412}{1075} = 3.17 \text{ lbs. of}$$

steam, no heat loss considered.

The efficiency of the electric steam generator is very high, the only losses are the radiation losses of the apparatus, and the heat losses represented by a certain amount of water discharged from the generator which carries away a certain amount of accumulated impurities in the feed water. By proper lagging and regulation of this discharge water the losses become very small and depending on the size of the generator may be from 1 to 4%—for larger sizes of generators the efficiency can be

taken around 98%. On this basis 1 k. w. h. will produce 3.10 lbs. steam. Under average conditions 1 lb. of soft coal of about 12,000 B. t. u. evaporates about 8 lbs. of water. 1 ton of 2,000 lbs. of coal evaporates 16,000 lbs. of water. The electric energy required to evaporate the same amount of water is equal to

$$\frac{16{,}000}{3.10} = 5{,}161 \text{ KWH.} = 215 \text{ KW}$$

days = .59 k. w. years = .8 h. p. year, or in other words 215 k. w. in an electric steam generator is equal to one ton of coal per day, burned under average conditions of boiler efficiency.

Comparing the capacity of an electric steam generator with the capacity of a regular boiler in boiler horse-power, we find the following relations: One boiler horsepower is defined equivalent as the evaporation of 34½ lbs. of water from and at 212° F. per hour and represents 33,479 H. t. u. per hour, 1 k. w. hour being 3,412 H. t. u. and at an average efficiency of 98% equal to 3,342. These figures are almost exactly in the ratio of 10 to 1, therefore, an electric steam generator of 1,000 k. w. capacity is equal to a boiler of 100 boiler horsepower.

Classes of Electric Steam Generators

Electric steam generators have been built during the last ten years in capacities up to 1,000 k. w., and only in the last two sizes of 2,000 k. w. and more have made their appearance. Steam generators may be divided into two main and distinct classes:

First—Generators in which the electric current passes through a combination of metallic resistors.

Second—Generators in which the water itself forms the electric resistance.

Metallic Resistance

In the first case the metallic resistors in the form of wire and ribbon of some high resistance alloy may be mounted in tubes similar to those in fire tube boilers. The arrangements allow the use of alternating or direct current as heating elements do not come in direct contact with water. In all other cases where the resistors are in contact with water and the current passes partly through metallic resistors and partly through water only alternating current can be used as direct current would decompose water into its elements hydrogen and oxygen. Generators of the metallic resistor type are only suitable for low voltages up to about 500 volts and are therefore not usually adaptable for very large outputs. The steam production is controlled by switching on and off of a number of parallel circuits and the combination of such circuits in parallel or series connection. To maintain a constant steam pressure requires, therefore, rather complicated and expensive electric control equipment. Generators of this type have been built of 1,500 k. w. capacity, being of the tubular type construction, about 20 ft. long and 5 ft. 6 inches in diameter. The space occupied by this type of generator is comparatively large compared with the steam generating capacity.

Water Resistance Type

The second class of generators which will be mainly dealt with in this paper are built on a principle quite different from the metallic resistor units. The electric current passes through steam tight insulating bushings to a system of stationary electrodes partly submerged in water, the water to be evaporated serves as the electric resistance. This type of generator is known as the "Revel Generator" and has been in use principally in Italy, Switzerland and France for the last ten years, mostly in self-contained units up to about 700 k.w. For any considerable amount of electric power only a three phase alternating current system may be considered as practical to-day. For small units and of voltages up to about 2,200 volts, the container itself forms the neutral point of the three phase system and is grounded. For larger capacity generators, especially when the voltage is in excess of 2,200 volts up to 12,000 volts, it will be advisable to split up the generator into three single phase units with three containers, each containing one electrode, the three containers form again the neutral point and are metallically connected together and grounded. Owing to the comparatively high resistance of the water and the many possibilities of arranging the electrodes, it is possible to make use of comparatively high voltages such as are used in general distribution of power in industrial plants, and the use of step-down transformers, the cost of which would be greater than the cost of the steam generator itself is obviated. In order to maintain a constant steam pressure the generation of the steam has to follow closely the demand of the steam which means the electric power input has to be regulated to suit the steam demand. This is done by the variation of the electric resistance, either by changing the submersion of the electrodes, or varying the specific resistance of the water by suitably adjusting the amount of water fed to the generator and by controlling the water discharged either continuously or at certain intervals, carrying with it the accumulated impurities in the water.

The outstanding advantages of the steam generator of the water resistance type compared with other types are its simplicity in construction, compactness, easy control, and its very low cost per kilowatt capacity which is very often the determining factor, especially for temporary installations or where flat rate power is consumed to fatten the load factor of an industrial plant.

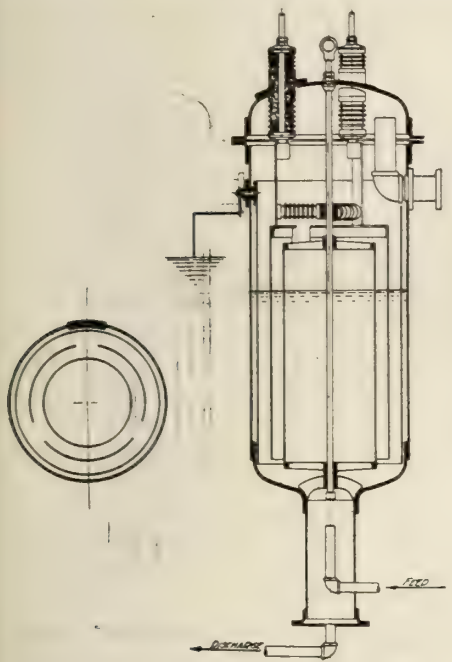
Construction Details of Water Resistance Type of Generator

The balance of this paper will deal only with generators of the water-resistance type. For a long time water has been used as a resistor of alternating current in various apparatus, mainly as energy absorber for electric generators under test and in starting devices for alternating current motors. In the latter case a salt is added to the water as otherwise the resistance would be too high. The use of water itself as an electric resistor for the production of steam is quite obvious though it requires a certain amount of investigation as to the suitability of different sources of water, the variations of the resistance of water at various temperatures and pressure and the practical limits in dimensioning the current path through water for various amounts of energy and voltages up to 12,000 volts. The resistance of chemically pure water is very high and of the order of an insulator, the resistance decreases with the contents of soluble salts—it is lower for spring water than river water. Condensate water, available in most cases where the electric steam generator is in use, is of a high resistance, but as it contains always from 20 per cent. to 40 per cent. make up water drawn from the river or other sources its conductivity is brought up again to quite a practical figure. In general, it can be said, that any water satisfactory for ordinary boilers is also suitable for the electric steam generator. The resistance of water has a negative temperature coefficient; that is, the resistance is decreasing as the temperature and the pressure rise. Considerable investigations and tests have been made by the writer to determine the relations of resistance and temperature for various kinds of water, and special apparatus has been built for this purpose for currents up to 10 amperes and 6,000 volts for tests under atmospheric pressure.

In the early stages of the development of the steam generator it was thought that the investigation of the relation of temperature and resistance of different kinds of water would be of great importance but it has been found later by experience in the operation of the steam generator that the resistance of the water in the steam generator could be controlled over a considerable range by discharging a certain amount of water from the generator. The purer the water and the higher the resistance the less water is to be discharged in order to maintain a suitable conductivity of the water.

Fig. 3 shows a section of a 5,000 k.w. generator, it consists of a vertical cylindrical tank with an extension at the bottom. The upper part is flanged and to it is bolted a dished cover which contains three openings for the porcelain bushings insulating the three copper conductors leading to the electrodes. The insulator bushing consists of three parts, two corrugated sleeves, one of which is outside and the other inside the tank and a tube inside these sleeves

which are held together by a shoulder and nut of the conductor passing through them. The faces of the sleeves are ground and are parallel and are made steam tight with the usual rubber steam packing. The packing also allows



Electric Steam Generator 3 phase single unit system.

a certain adjustment for the difference in the expansion of porcelain and copper. The porcelain sleeves are subjected to considerable pressure and are made rather heavy for mechanical reasons and with electrical characteristics suitable for at least 6,600 volts working pressure between the phases. The conductors support through a system of adjustable links the steel electrodes of curved plates arranged in a circle equidistant from two cylinders, one outside and one inside, forming the neutral point of the 3 phase system, the outside fastened to the generator shell proper and the inside suspended from the cover and well secured in a central position. Both these cylinders are electrically connected to the body of the generator and grounded. The arrangement shown in Fig. 3 is for 1,300 amperes, 2.200 volts, 3 phase, 60 cycles and for a working pressure of 165 lbs. per square inch. The electric current passes through from both sides of the electrode to the inside and outside cylinders, and to a much smaller amount directly from electrode to electrode.

Floor Space and Operating Details

The floor space required by these types of generators is very small, the 5,000 k. w. generator with electric control apparatus can easily be placed in an area of 10 x 12 ft., and the 18,000 k.w. generator, equal to 1,800 boiler h. p., with all its accessories will need a floor space of about 15 x 22 ft., and a head-room for easily dismantling of 25 ft.

The operation is extremely simple for the small generator and where they are not working in parallel with other steam plants, the operating can be made automatic by means of a regulating valve actuated by the pressure and controlling the amount of discharge water, thereby changing the water level, which, in turn, governs the power input and steam production and at the same time keeps the steam pressure constant. For large units and especially where they form only a smaller part of the existing steam plant and are therefore, not able to control the pressure alone, automatic regulation is not so simple, but the attention required is so small that one man could easily handle the operation of two to three very large units. For the electric control of the steam generator the usual apparatus such as disconnecting switches, oil switches, and preferably three ammeters to show the balance in the three phase, is required. Power measuring instruments may be added, depending on the nature of the power contract and supply.

As the heat in the steam generator is produced in the water there are no parts subjected to a higher temperature than the temperature of the steam. This means that no dangerous stresses are produced by temperature differences and this adds further to the safety of the apparatus.

There are other advantages of the electric steam generator over the usual coal fired boiler, for instance any interruptions to feed water supply simply means the shutting down of the generator and does not introduce any danger. The steam generator is equipped with the usual steam safety valves and can in addition be supplied with automatic blow-off valve which discharges the water and thereby shuts down the generator should the pressure go beyond a fixed limit. Other safety devices consist in relay protection of the electric circuit in case of short circuit, unbalancing or ground on the electric system, and a trip for the automatic oil switch, which will interrupt power and therefore the steam supply. It can be seen therefore that the operation of the steam generator is just as safe as, if not safer than the ordinary boiler and the insurance companies have no hesitation in accepting insurance on this apparatus in the usual manner.

Conclusions

1. The generator of the water resistance type is safe and easily controlled.
2. The apparatus can be installed in a very small space close to where the steam is required. Its design and operation are very simple and only needs the attention of an ordinary skilled man.
3. The generator is the cheapest electric method of converting electric energy into heat.
4. For the consumer of power the generator means the utilization of any idle power and thereby the improvement of the load factor.
5. The power company is able to sell its surplus power for the generation of steam which is made possible mainly by the fact that the first cost and installation of the steam generator is comparatively low.
6. By the introduction of such a simple and cheap device much idle electric power can be utilized, which in itself means a further step in the conservation of our natural resources.

REFRIGERATION TALKS IN PLAIN LANGUAGE

Continued from page 21

the second case that you have in the first. A better illustration can be found in the case of watts, in the electrical measurement. If you have 100 amperes at 100 volts, you have 10,000 watts. If you have again 10 amperes at 1,000 volts, you still have 10,000 watts, while if you have 1,000 amperes at 10 volts, the number of watts has not been altered. You have a small current flow at a high pressure, or a high current flow at a low pressure, the resulting power being the same.

It is the same with heat and temperature. You can have a large quantity of heat at a very low temperature, and the same amount of heat but at a high temperature level, but in order to obtain work, we must have a drop from a high temperature to a lower one. We cannot obtain work by going from a low to a high temperature level. In order to do this we must perform work. If these points are borne in mind we have the way clear to study their application in the art of refrigeration by mechanical means.

OTTAWA LODGE C. A. S. E.

Ottawa Lodge No. 6, C. A. S. E., held another open meeting on Wednesday evening March 22nd. Mr. Arthur G. Pedder, A. M. E. I. C., assistant chief engineer of the Ottawa Electric Co., gave the members and visitors a treat, demonstrating by aid of lantern slides the inner workings of the steam turbine, using over fifty slides.

He specially explained and dealt with blades, nozzles, governors, lubrication and operation of the steam turbine.

There were a large number of members and visitors present, who enjoyed very much the plain, simple, and instructive manner with which he explained his subject.

Mr. Pedder, who has had a very wide practical experience with large turbine plants, feels very much at home with his subject, and Ottawa Lodge very much appreciate his membership.

Steam Consumption of Soot Blowers

Some Interesting Charts Have Been Produced From Data Obtained at a Large Power Plant. This is the First Time This Information Has Been Made Available

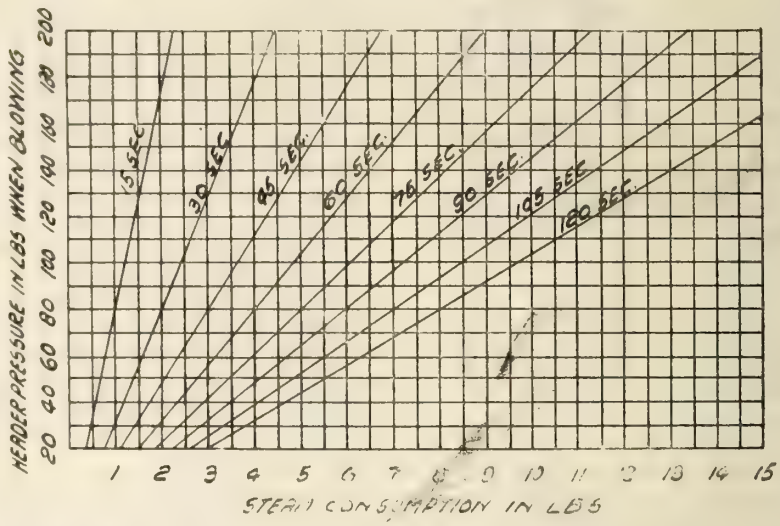
By ROBERT JUNE

ONE OF the outstanding features of the new valve-in-head type of soot blower is the steam saving effected, the unit valve being open just long enough to have the jets pass over the part of the tubes to be cleaned. With the cam adjusted to hold the valve open for 300 deg. the head uses steam from five to seven seconds per revolution. As the gear reduction assures turning of the element slowly and steadily, it is rarely necessary to revolve the blower more than two or three times. This means that steam is being used from fifteen to twenty-one seconds per unit per blowing.

In contrast the valve of the plain revolving soot blower is necessarily open from 45 to 75 seconds, 60 seconds being the average time required for close attentive operation.

At this point it is well to observe that very few men operating soot blowers realize the importance of giving proper attention to the steam loss due to unit valves being kept open longer than necessary to clean the boiler properly. We have timed a large number of soot blower operations, many of them without the knowledge of the operator, and it has been surprising to note the frequency with which the unit valves are kept open two and three minutes and even longer, while keeping the valves open from a minute and a half to two minutes is common practice.

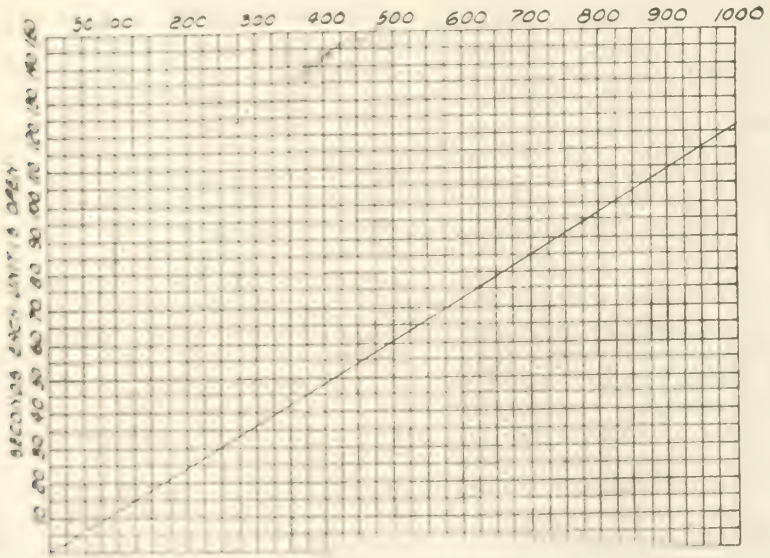
Fig. 2 is a chart from which the steam loss from excessive blowing can readily be computed. The vertical column of figures at the left is the steam pressure in the header when blowing, while the figures at the bottom show the amount of steam that will pass through a standard 5/16in. soot blower nozzle at the various pressures in a given time.



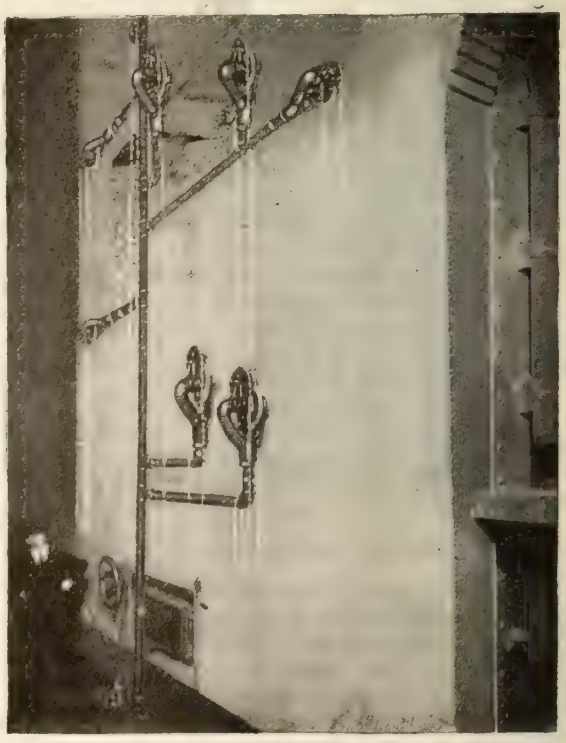
HEADER PRESSURE IN LBS WHEN BLOWING
20 40 60 80 100 120 140 160 180 200
15 SEC
30 SEC
45 SEC
60 SEC
75 SEC
90 SEC
105 SEC
120 SEC
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
STEAM CONSUMPTION IN LBS

Steam consumption for single 5/16 in. jet. Header pressure 40 to 200 lbs. when blowing. Valve 15 to 120 seconds.

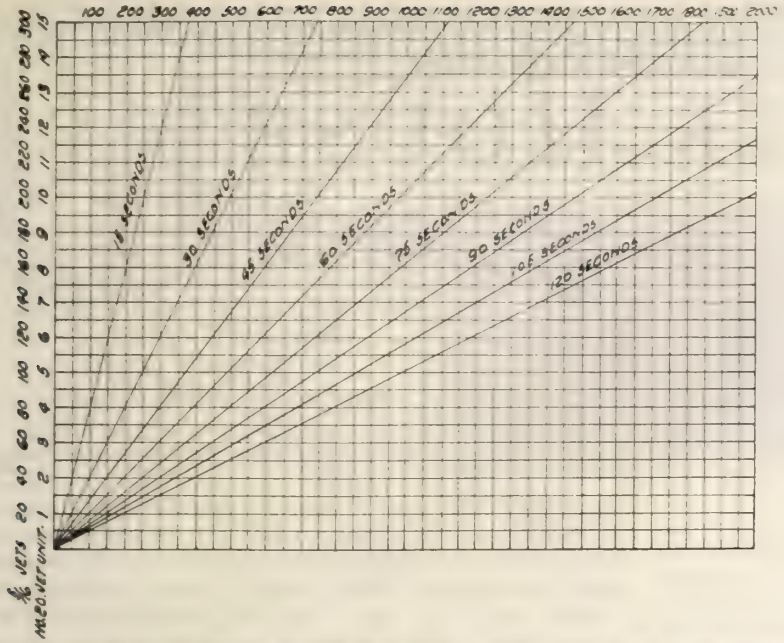
The point at which the slanting lines intersect vertical lines for a given pressure indicates the steam flow through the nozzle for the time marked on each slanting line. By this method we find that with 100 lbs. header pressure, 2.4 lbs. of steam will flow through a nozzle if the valve is open 30 seconds, while 9.6 lbs. will be used if the valve is left open 120 seconds. Taking a standard 21 wide B & W boiler, we find we have five units of 20 jets each or 100 jets. To blow this boiler by the valve-in-head



Steam consumption in lbs. per 5 units on boiler 21 tubes wide. 100 lbs. header pressure. when blowing.



Valv-In-Head Soot Blowers.



Steam consumption per unit for boiler 21 tubes wide. Header pressure 100 lbs. when blowing. Valve open 15 to 120 seconds.

system with the valves open 30 seconds each will require 240 lbs. of steam, while with the independent valve soot blower if the valves are open 120 seconds each, 960 lbs. of steam will pass through. If the boiler can be properly cleaned with the valves open 30 seconds, the loss would be 720 lbs. per blowing, or 2,160 lbs. in 24 hours, if the blowers were used three times a day. With the boiler in service 300 days a year, the steam loss would be 648,000 lbs. To reduce this loss to dollars and cents it is only necessary to multiply the cost of the steam from 20 to 70 cents per thousand lbs., by 648. If the steam costs 50 cents per thousand lbs., the loss for the boiler described above would be $324.00 per year.

The chart, Fig. 3, shows the total steam consumption for a five unit 21 wide installation, on which the header pressure is 100 lbs. with the unit valves open from 10 to 130 seconds. Figure 4 shows the total steam consumption of installations on a 21 wide boiler with 100 pounds header pressure, having from one to fifteen units and blowing from 15 to 120 seconds each. From this it will be seen that a boiler with 14 units, having 20 jets each, and with 100 lbs. header pressure, will require 690 lbs. of steam per blowing, if the valves are open 30 seconds each, while 1,725 lbs. will be required if the valves are left open 75 seconds each.

It should be noted that the pressures given are for the header while blowing. With one unit valve open the header pressure will be from 50 to 80 per cent. of the boiler pressure, depending on the size of the piping, the bends and valves in the line, the number of jets on the unit and other conditions. The header pressure will always be somewhat higher than the pressure in the blower element, due to friction between the header and the element and in the element. This will also account for the discrepancies between these charts and the results obtained by the use of Napier's Formula.

These charts have been compiled from data collected while making tests on soot blowers at one of the largest power plants in the United States under conditions which assure their accuracy.

HELP FOR RUSSIAN ENGINEERS

The following circular letter has been received by "Power House," and as there may be among our readers some sympathisers with Russia in her present troubles, we are re-printing it just as received. The letter is issued by the Engineering Section of the Society for Technical Aid to Soviet Russia, 110 West 40th Street, New York. We are not aware who is behind this society, and it may be noticed that no names are given, even the secretary neglecting to give his name. Under these circumstances, we leave it to our readers to judge the letter on its merits.

Dear Sir:

The Engineering Section of the Society for Technical Aid to Soviet Russia has been requested and appealed to by the Russian scientific and engineering societies for books, bulletins, pamphlets and current literature on the scientific and industrial progress in the United States, particularly since 1914.

Our individual members have donated toward a fund created by the engineering group in order to send such literature to Russia. The demand, however, is so great and the needs for the latest available scientific and technical publications are so urgent for Russia's industrial rehabilitation, that they cannot be fulfilled by the Engineering Section of the S. T. A. S. R.

We, therefore, take the liberty of requesting you to aid us in answering this appeal from Russia, and if possible send us back-numbers of your publications as well as recent ones, since your publication has been mentioned by the engineering and scientific societies of Russia as worthy of technical and scientific reference.

We are mindful of the fact that America has already done a great deal toward the alleviation of the starvation sufferings of Russia, and we trust that by issuing this appeal in the name of Russian scientific and engineering societies we will not have taxed the generosity and kindness of the American people.

We are certain that in the very near future, when Russia shall have returned to normal conditions, the Russian engineering and scientific societies will gladly reciprocate and send free of charge their new publications, if not to all, at least to replenish the files of the American libraries, which are at present incomplete without the latest publications from Russia.

Many of our readers, possessing your publication might be willing to contribute it for this worthy purpose, and we take the liberty to suggest that you give this appeal editorial mention.

Thanking you in advance for your courtesy, we remain,

Very respectfully,

Secretary, Engineering Section.

BRITISH HYDRO-ELECTRIC INSTALLATION

A water power station with some original and most interesting features has just been completed in Scotland. A small head of water had been used for a long time in driving two mills by old-fashioned breast wheels. Owing to the increasing demand for power the question of reorganizing the installation became pressing. It was eventually decided to use the water power for generating electricity and to augment the supply of water power by arranging a high level reservoir into which the water could be pumped during the hours when the mills were not working. Actually the mills work for about 50 hours per week. During these working hours the water runs down from the high level reservoir through the same pipe up which it had previously been forced, and it drives a Pelton wheel which generates the additional power required. This plan has frequently been discussed by hydraulic engineers, especialy in connection with tidal power schemes; but this is the first time it has been actually carried out. The results have been entirely successful and reflect every credit upon the engineers who designed and carried out this novel scheme. The equipment consists of two low pressure turbines of 110 horse power each, while the Pelton wheel runs at 1,000 revolutions per minute and drives a 155 kilowatt generator.

Pride In The Job

IN ANOTHER section of this issue is a letter from a correspondent, taking us to task for making what appears to him to be invidious comparisons between the saw mill engineer and the ordinary plant engineer. In order to show us that we were doing the sawmill an injustice, he sent along with his letter of protest a number of cards taken from the different units under his charge. These cards have been reproduced with the letter.

We have also written to the gentleman sending this asking him to give us for the benefit of our readers some more details of the plant and its problems, which we feel, cannot be anything but helpful to others. The point we chiefly wish to bring out in connection with this letter is the evident pride that our correspondent takes in his job and its responsibilities. He has the spirit which is necessary to every power plant engineer who is going to be a success in his business. The plant in his charge is not merely something that occupies him for so many more or less hours during a week. It is more than that. It is a standing testimony to the interest the engineer takes in it, and a reflection of his ability, or otherwise.

We remember an old chief engineer in our seagoing days, who at the end of a run, when the engines were finally finished with, used to walk down the ladder, and take a turn round the engine room, giving the engines little affectionate pats here and there on the way. To him, those masses of metal were something of himself, which responded to the treatment they received.

This is the spirit to cultivate, the spirit that makes the hours pass by like minutes, that sends a man home at night with the feeling of something done that has been worth while. The spirit that is reflected in the smoothness of the running of the plant under his charge. The spirit that makes itself evident the moment one steps into the engine room, and makes one say, "Here is the plant of a man who has pride in himself."

Call it self respect, "esprit de corps," or what you will, it has a wonderful influence on a man's life and a man's work. It is the same spirit which moved Paul of Tarsus when he said, "I am a citizen of no mean city." The engineer who possesses it may be in the smallest job in the country, but before the end of his career he is going to be not far from the very top.

Be proud of your job, and your job will show you reasons for being so.

Something Wrong Here

AN EMPLOYEE of a brickyard in Toronto was killed the other day while attempting to put a belt on a shaft while in motion. The end of the shaft projected beyond the pulley, and the unfortunate man was dragged, caught through his clothing on the end of the shaft, and practically smashed to

Some interesting facts anent the system of factory inspection were brought out during the inquest. First of all, it was established that no copy of the factory act had been exhibited in the place for over five years. It was over a year since there had been a factory inspector in the place. One factory inspector giving evidence, said the place used to be in his district, and when under his jurisdiction he had ordered some guards to be placed around shaft or pulleys. He had been to the factory since the accident, but didn't notice whether his recommendations had been carried out or not.

The inspector now in charge of this district admitted that he had not made any visit to the place before the accident, giving as his reason that he did not know of the existence of the factory. He stated that when an inspector took over a district, he had to hunt out the factories in it, as there was no list provided.

There is a strong supposition from the evidence given at this inquest that had this accident not occurred, everything would have gone on in the same old way until something did happen. Preventive measures were not considered, and it does not seem to have been any one's business to look into the matter. There is a safety league convention in Toronto this week, preaching the gospel of safety first. There is a factory inspection department, and there are inspectors appointed and drawing a salary for preventing just such accidents as the one under discussion, yet according to the evidence of one of these inspectors the department has no information of the factories supposed to be under its jurisdiction. The inspectors have to "hunt these places out."

What seems to be needed is a factory inspection department that will inspect.

Errors In Formulae

WE RECEIVED an enquiry from a correspondent this week anent an answer to a question in the issue of November 5th. He wanted to know where we got certain figures. Looking up the answer in question, for the moment we did not know where they came from ourselves, until we recognized that once again the staff in the printing department had introduced some figures from their own private stock. In this particular case they merely put a figure 3 in the front and a cipher at the end making 1,200 into 312,000.

We recognize the confusion that is caused in the minds of readers by these unfortunate mistakes, and are doing everything possible to eliminate such happenings. In a publishing house of this kind where such a large number of journals are published during a month, we have to work at high pressure. The ordinary compositor or linotype operator does not realise that a figure altered in a formula is a much more important matter than a letter misplaced in a word with which every one is familiar. We have also been handicapped to some extent by changes in the staff.

We would ask our readers to co-operate with us by calling attention to any error which may have got past us, and appears in print. We will on our part try to make it impossible for the reader to find any. We feel keenly any annoyance caused to a reader who has asked for information, and through a typographical error, gets something of which he cannot make head or tail.

The Operators' Point of View

STANDS UP FOR SAW MILL

Editor, Power House:

I am herewith enclosing some indicator cards (mostly from sawmill engines) which will be a surprise to you, according to your rating of sawmill power plants and engineers in your valuable paper. I note in reading your articles you always contrast the sawmill plant with some up-to-date power plant when describing the salient features of the latter. This has been the prevailing opinion about sawmill power plants

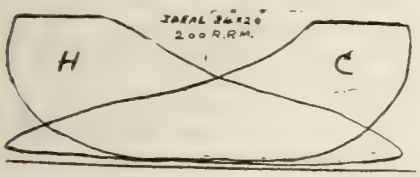

Fig. 1. Ideal engine made by A. L. Ide & Co., 24 x 20 inches 200 R.P.M.

until these last few years, and to-day some people still hold this opinion.

The sawmill of old usually had a few old boilers in a shed, and an old box-bed engine hidden in the saw-dust somewhere, barking out steam, and a chief engineer who could attend to the various duties of blacksmith, oiler, fireman, boiler washer, steeple jack and do his own brick laying and furnace work, which required brawn and not brain. Today the engineering department of a sawmill is the most important of all, as they have up-to-date engines, steam appliances for turning logs, controlling carriages, and giving motion to various devices such as raising bumpers, stops, rolls, and other heavy parts, that all used to be moved

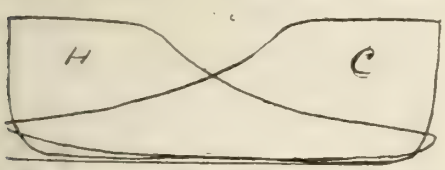

Fig. 2. 22 x 48 inch Murray Corliss engine, single eccentric.

by hand. In fact one of our mills had no less than forty-seven steam cylinders used for the aforesaid purposes.

There is also an air pressure to maintain in a modern sawmill. Right here we have a lumber trimmer with twelve air cylinders and air pressure is used for many other purposes.

Then comes electricity for lighting and power. The Big Rivers sawmill has a one thousand k.w. generator for power and a two hundred and fifty k. w. gen-

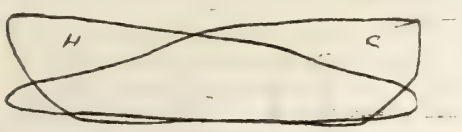

Fig. 3. Goldie & McCullough 16 x 24 slide valve engine, box red pattern.

erator for lighting, both direct connected to up-to-date Corliss engines.

Again there is the fire protection apparatus. We have here (at the Pas) five sprinkler systems with about 270 heads on each system with the necessary pumping equipment, tower tanks, etc., which are kept in working conditions (at a temperature of 50° below zero at times during the winter months). It must be taken into consideration also that sawmill boilers carry a higher pressure than formerly and are not usually situ-

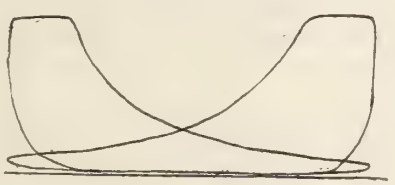

Fig. 4. Nordberg Corliss engine 24 x 48 inches. One eccentric for steam and exhaust, and a separate eccentric for knock off gear. This is set in line with crank giving practically full stroke range of cut off.

ated in a locality favorable for good feed water in this western country, which entails considerable work and extra care to keep boilers clear and in good condition for work and sometimes a large overload has to be carried on same.

We also design some of our equipment, have the patterns made and do the machinery of same right on the ground, so that saw-mill engineers and equipment should have a better rating than is credited to them in most tech-

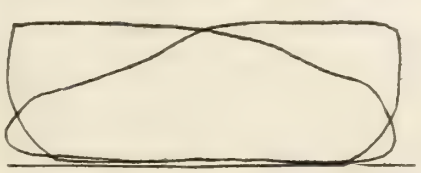

Fig. 5. Twin slide valve engine 16 x 22, built by Houston, Stanwood & Gamble, Cincinnati.

nical journals, and I think, Mr. Editor, that if you visited a real saw mill you would agree with me and not give all the superiority to hotel power plants as in your issue of Power House for February 1922.

Yours very truly,
Allen Norgrove
Chief Engineer
Pas Lumber Co.
The Pas, Man.

BANKING FIRES

By James E. Noble

Before banking the fire, the grates should be cleaned and what fire remains should be piled against the bridge wall upon the back shelf of the grates. Fresh coal is then added in a thick layer over the banked fuel and the fire is left with the ash pit doors closed, the fire door open and the damper closed or nearly so. The closing of the ash pit and the opening of the fire door makes the ignition of the bank of fresh coal very slow, so that some time will elapse before it has become ignited, when it will burn slowly.

In starting up, the fire should be cleaned and spread, when it is ready for the next run. Banking fires, in operating return tubular boilers, is a thing nearly every engineer has done some time in his life, and it is a surprising thing to learn in how many different ways the job is done. Each man seems to have some little kink of his own devising, which he feels sure, in his own mind, tends to make a good bank better.

In the event of restricted coal production in the States, as a result of the miners ceasing operations, it is expected that adequate supplies will be received from Britain to take care of Canada's needs. Inquiries are now being made in London freight circles as to rates on coal shipments to Canadian ports.

Large additions will be made to the cold storage plant at Grimsby, Ont. For several seasons this warehouse has been operated under the direction of the Dominion Department of Agriculture as an experimental plant, but has been turned over to the Growers' Cold Storage and Ice Co. Under the new arrangement the capacity of the warehouse will be quadrupled, and improved refrigeration will be installed, as well as mechanical facilities for the manufacture of ice.

OUR QUESTION BOX

Questions are invited from readers regarding power plant operation and difficulties encountered

C.A.S.E. Competition Questions

Toronto No. 1 Lodge

Q.1. What is meant by the total heat of steam? How is this calculated?

A. 1. Total heat is the heat required to change water from 32 Fahr. to steam at 212 Fahr. It is calculated by latent heat plus the sensible heat.

Q. 2. What instruments are necessary for conducting a capacity test on a boiler? Give a description and reasons.

A. 2. Scales for weighing coal also one for weighing water, or meter it. Two tanks, thermometers, calorimeters, draft gauge, barometer, rheostat, phychometer, watch or clock.

Q. 3. What additional instruments are necessary for plotting a heat balance?

A. . Steam-flow meter, recording pressure and temperature meter, also recording C O$_2$ meter, vacuum gauge in cases of condensing.

Q. 4. Give a description of how you would proceed to conduct an evaporation test and sample log for recording essential facts?

A. 4. Raise steam to working pressure, remove quickly all fire from the grates and clean ashpit as quickly as possible, start a new fire with weighed coal and wood, noting the level of the water in the gauge glass and marking it just before lighting fire. During the test weigh all coal and water taking the temperature of the feed water from the tanks at each filling, also maintain the height of water at the same level during test at the end of test draw fire and weigh the ashes and fire drawn, water level, should be the same as at commencement of test and everything should be kept as uniform as possible and a record of every occurrence taken. Time of each firing, amount of coal used at each firing and time taken to consume each firing. (Sample log at end.)

Q. 5. What is a steam flow meter? Give description and operation.

A. 5. A flow meter measures the amount of steam passing from the boiler.

Q. 6. Explain why with an orifice and U tube the fluctuations are in direct ratio to the flow of steam?

A. 6. Because of the relation of flow or velocity to pressure; or the dynamic to the static pressure, by reason of which the differential is transmitted to the chamber where electrical contact is registered.

Q. 7. Why is mercury used as a measuring agent in preference to any other medium?

A. 7. Because its specific gravity is not easily subject to change by freezing or evaporation and its P. T. O., coefficient of expansion.

Q. 8. Give reasons why in your opinion steam flow meters are necessary for boiler operation and also why the fireman should be conversant with their use?

A. 8. By means of steam-flow meters it can be readily determined if the boiler is delivering its rated capacity, and more accurate determinations as to evaporation may be arrived at. (Efficiency rating).

Q. 9. What reasons have you for advocating the use of the steam flow meters in the various departments?

A. 9. To distribute the cost to each department according to steam used by each department.

Q. 10. Why is it more desirable to have a meter on the steam header than on the feed water and what information would you expect to get if you had both lines metered?

A. 10. The meter on the steam header would register the steam sent to the users and the meter would not record what would be lost by blow-downs, leakage of valves or safety valve, blow offs.

Int. and Depreciation Charge on Heater $.....; Int. and Depreciation Charge on Economizer $..... Net Saving Effected by Heater $.....; Net Saving Effected by Economizer $ .....

NOTE.—Savings may be effected not only by the use of the heat of exhaust steam and flue gases, but by the introduction of automatic damper regulators, C O^2 recorders, and steam flow meters all of which may be treated in the same way as the gains shown by use of F. W. Heater and Economizer.

Combined efficiency of boiler and engine may be determined more readily by the use of steam flow meters than by any other method.

ORDERING PISTON RINGS

Question: — Would you inform me through the Question Box the correct way to order piston rings for steam cylinders, also gas engines. How does one give the dimensions?

Answer:—The dimensions necessary are the depth, width, and the diameter of cylinder bore. This will be sufficient for the machinist to make the ring from. Piston rings should always be turned slightly eccentric, that is they should be thinner radially at the point where they are cut than at any other point. This is to allow them to assume a truly circular shape when in the cylinder. The amount is very slight, and many rings are made without adopting this precaution, especially in small sizes.

HEATING SURFACE

Question:—What is the ratio of heating surface to cubic foot of air space? Is it standardized throughout Canada?

Answer:—The amount of heating surface per cubic foot of air space will depend on the temperature inside of the coils, and the temperature of the room to be heated. A pound of air has a volume of 12.36 cubic feet, and the specific heat of air is .24. Therefore to raise 12.36 cubic feet of air one degree .24 B, T. U. will be required, or 1 B. T. U. will raise one pound of air 4.165 degrees, or one 4.165 lbs. 1 degree in temperature. The heat loss from coils is usually taken as about 2 B. T. U. per degree difference per sq. foot heating surface per hour. Suppose we had a room 10 x 10 x 8 or 800 cubic feet, and we wished to raise the temperature from 0 to 70 degrees. The B. T. U. required would be

$$\frac{800 \times .24 \times 70}{12.36} = 1085$$

and if the coils contained steam at 212 degrees, then 212—70=140, and if the loss was 2 B. T. U. per square foot per degree difference per hour, that would give us 280 B. T. U. per hour, and 1085 divided by 280 would be 3.8 square feet or say 4 square feet surface. If hot water were used instead of steam about 8 feet would be needed. If the air was to be changed twice an hour double the amount of surface would be required.

SAFETY VALVE SPRING

Question:—Referring to the 5th November article issue, page 40. A boiler has two safety valves each 3½″ in dia., size of wire is ⅝″ square. What should be the allowable pressure on the boiler, the grate surface, the diameter and length of spring?

You don't show the allowable pressure here, you show 9.6 x 125 = 1200 lbs. = the load on spring and one formula for the spring of a safety valve is

$$d^3 = \frac{S \times D}{C}$$

Where d=diam. or side of wire.
S=load on the spring in lbs.
C=11,000 for square steel.

Now we come down to

$$.625 = \frac{31.200}{11.000}$$

Where do we get the 31.200? What is it?

I am enclosing another formula, which I cannot follow. Can you explain it? G. K.

Spring ⅝ = .39 = 600 or 1/16 of breaking load.

$$\frac{600 \times .39}{25} = \frac{23,400.00}{25}$$

$$= 936 \text{ lbs.}$$

$$\frac{936}{9.62} = 97 \text{ lbs.}$$

$$97 + 15 = 112$$

$$\frac{37.5}{112} = .334 \text{ area of valve.}$$

in square inches to grate surface in sq. feet.

Outside diameter of spring

$$\frac{.625 \times 3}{.5} = 3.75$$

Length of spring

$$\frac{.625 \times 11.5}{.5} = 14\tfrac{3}{8}$$

Answer:—In the working given in the November 5th issue, a pressure was assumed, and the rest of the dimensions calculated from that. The figure 312,000 was a misprint, and should have read 1,200, as can be seen by the remaining part of the formula.

In the formula above that you have sent along, the working pressure has been found by making another assumption. Here the working strength of the spring has been assumed to be 600 lbs. per square inch. The .39 is the square of .625, and 600 × .39 gives the strength of the section assuming that 600 lbs. per square inch is allowed on the metal. The 25 given in your copy of the formula should be .25, and is the cube of .625.

This is as far as we can see without any explanation, and this has been used to get the load on the spring, given as 936 lbs.

If we apply this load to the formula for the mean diameter as given by recognized authorities we get

$$d = \frac{S \times D}{C}$$

where d is the diameter or side of wire, D the mean diameter, and C a constant 11,000 for square steel.

This gives, using the figures for the load as found in the formula you have sent

$$.244 = \frac{936 \times D}{11,000}$$

$$\text{and } D = \frac{11,000 \times .244}{936}$$

which gives a mean diameter of 2.8 as against 3.75 given by your formula, a little further down.

If we take the mean diameter as found by your formula 3.75 and apply it to find the load we get

$$d^3 = \frac{S \times 3.75}{11,000}$$

$$\text{and } S = \frac{11,000 \times .244}{3.75}$$

$$= 715 \text{ lbs.}$$

The results obtained do not agree with each other.

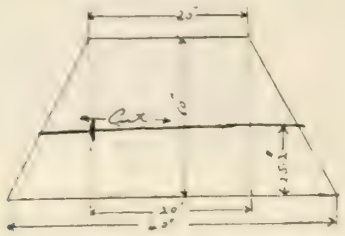
We should be glad to have the explanation of this working for the information of our readers.

A MENSURATION QUESTION

Question:—Please work out the following problem by arithmetic. I have worked it out by Algebra but would be glad if you would work it out as requested. How would you figure out where to cut the following sheet of iron so as to have the same weight in both pieces, the cut to be made in the direction of the drawing?

Answer:—We have in this figure prac

tically a parallelogram 60 inches high and twenty inches wide, and two triangles, each sixty-inches in height by 10 inches base. These can be considered as



one triangle with a base of 20 inches and a height of 60 inches. The centre of gravity of the parallelogram is at half its height, while the centre of gravity of the triangles is at one third its height. The height of the centre of gravity of the triangle is then two thirds of the height of C. of G. of the parallelogram, and the difference between the two heights is one third of the height of the centre of gravity of the parallelogram.

We then have two thirds of the weight concentrated at one half the height, and one third of the weight concentrated at one third the height. If we divide ten inches, the diference between the two by three, we have 3.333 inches, and twice this is 6.666. If then the centre of gravity of the one third is moved up two thirds and the two thirds moved one third we get a mean centre of gravity of 26.666 from the bottom.

A line cut across this point will not give us an equal weight each side, although that is the spot where the centre of gravity is concentrated, and if suspended thereby would be perfectly balanced.

We would have a parallelogram measuring 31.111 inches on the top, by 40 inches on the base, the area of which is 40 plus 31.111 × half the height, which is 13.33 inches.

This 31.111 plus 40 × 13.333=945.88 square inches area. We have thus an excess of 45.88 square inches below the line of the centre of gravity, and the area above will be 854.12 square inches. At the width of the figure 26.6 inches from the bottom, it would require a depth of 1.47 inches to give the requisite amount of area, that is we should have to subtract 1.47 from 26.6 to give the position of the line of cut. The width however increases by .333 inches for every inch nearer the bottom of the figure. We would have then a parallelogram with a mean width 35.8 and a height of 25.19 inches from the bottom, which would give us an area of 901.802 square inches. If we subtract .03 inch from 25.19 we shall get the exact division. Thus 25.16 height and a mean width of 35.8 gives

$$25.16 \times 35.8 = 900.728$$

which is close enough for all practical purposes.

Suppose we take the areas direct without finding the centre of gravity. We have taken areas on each side of the centre line horizontally, first

$$35 \times 30 = 1050$$

and the top part

$$25 \times 30 = 750$$

Thus we have a difference of 300 square inches between the top and bottom halves. That means our dividing line must be brought down below the centre, an amount sufficient to give an area of 300 square inches. Now if the figure were the same width all the way, we should simply have to move the line down 15 inches. We have, however, a gradual increase in width at the rate of one third of an inch in width for every one inch we approach at the base. At 20 inches from the base we should have a width of 33.333 inches, and the width at 25 inches would be 31.666. Assume this to be the width and divide it into 300 we have 9.47 inches. Taking half of this we have 4.735 and subtracting this from 30 we have 25.265. We have then practically the same result as before.

SPEED REGULATION

Question:—An engine runs at 236 revolutions per minute when under full load, and 240 revolutions when under no load. What is the percentage regulation to the governor? How would you make such a calculation, and why would one desire to ascertain this percentage?

Answer:—The percentage of regulation would be found by the proportion of the full load revolutions to the no load revolutions as compared to 100, and subtracting 100 from the result. Thus

$$236 : 240 :: 100 : x$$

$$\frac{240 \times 100}{236} = \frac{24000}{236} = 101.78$$

Subtracting 100 from this gives 1.78 per cent. increase, and this is the percentage of regulation.

In electric lighting plants, where the load is unsteady, the closeness of regulation to the governor is important, as otherwise the lighting will be subject to flickering. Again, if there are a number of motors on the circuit which are being thrown on and off, or their load is subject to sudden fluctuations, if the governor cannot regulate the speed of the engine closely, the voltage would be liable to rise very suddenly, with perhaps such results as burnt out insulation, or at least blown fuses, or the throwing out of circuit breakers. Such engines are therefore usually specified to have a regulation of 2 per cent. from full load to no load.

COOLING SURFACE IN CONDENSER

Question:—I have obtained through the Question Box information on the work done by a particular machine in tons of refrigeration, and I would like to obtain the following information. How much condenser of the double pipe system is required for one ton refrigerating capacity? In a direct expansion system how many square feet of cooling surface can be handled by one ton refrigerating capacity? (Any temperatures can be used for example). In speeding up a machine to increase its capacity, on a system that is deficient in condenser surface what is the result?

Answer:—The usual allowance for double pipe condenser is 20 feet of 1¼ pipe per ton of refrigeration. This is equivalent to about nine square feet of cooling surface per ton. The rate of heat transfer from ammonia depends on the temperature of the cooling water, and the velocity of the water passing through the pipes. This velocity is of course dependent on the pressure, and an increase of water velocity at the same temperature conditions will give an increased cooling effect for the same amount of surface. While there are many factors influencing the heat transfer, the temperature and velocity are the principal ones, and this amount of cooling surface has been adopted by leading makers as the result of wide experience, to suit average conditions.

The number of square feet of surface that are required in the direct expansion coils will depend on the temperature. To produce one ton of refrigeration per twenty-four hours with a condenser pressure of 139 lbs. and temperature of 80 degrees, and a suction pressure of 16 lb. and zero temperature, 3.74 cubic feet of gas must be pumped per minute. Assuming that the liquid in the coils is fully evaporated, and the coils were 2 inches inside diameter, there would be 3.74 x 1,728 equals 6,642.72 cubic inches. This divided by the area of the pipe which is 3.1416, is 2,057 inches or 171.4 feet. This is equal to 95 square feet surface. A ton of refrigeration is 288,000 B. T. U. per 24 hours, and 12,000 B. T. U. per hour, so with 95 square feet of surface in the direct expansion coils this would be equivalent to a heat transfer of 127 B. T. U. per square foot surface per hour. One authority gives as a fair practical estimate between 200 to 250 feet of 1¼ pipe per ton refrigeration. It is better to make a liberal estimate, to allow for operating conditions which may cut down the efficiency of the coil. The result of speeding up a machine with insufficient condenser capacity can be deducted by considering the action of the gas. It must be remembered that the heat taken up by the ammonia in the expansion coils or evaporator, together with the heat of compression, has to be rejected in the condenser. Speeding up the machine means that more gas has to be handled, and if there is not sufficient capacity in the condenser, the temperature and pressure on the condenser will build up. This means that the engine has to do more work, if the temperature and pressure of the evaporator or expansion coils is kept the same.

The extra temperature of the liquid passing the expansion valve will decrease the available refrigerating effect of the ammonia per lb., and the net result will be that you are handling more gas, and using more power to drive the machine, without any gain in cooling effect. The closer the condenser pressure and temperature are to the evaporator pressure and temperature, the less work has to be done by the machine.

CONCRETE MIXING

In some plants the jobbers do much of the repairs to the floors, etc. In laying concrete floors in boiler rooms the following item may help. In proportionizing, the following may be used. One part best Portland cement, 3 parts of clean sharp sand and 5 parts of stone, broken small enough to pass through a two-inch screen. In preparing the concrete, the sand and broken stone must be first carefully washed clean just before being used, then the cement and broken stone and sand are mixed together and an additional amount of water added by means of a spray to form a pasty mass. It can then be placed in position and pounded down with a light ram. The surface is then finished with a half inch coat of cement in proportion of two parts of cement to one part of fine clean white sand and finished with a floated surface. The body of the concrete should not be allowed to dry before the finishing coat is applied. The foregoing will give a good durable floor. Some men advise using sifted ashes, in a smaller proportion, instead of the sand, and well washed broken clinkers, instead of the stone. This will make a cheap job, and in appearance equally as good as the sand and stone floor, but like most cheap jobs, it will be far less durable, and much less liable to withstand the rough usage usually applied to boiler room floors.

Boring for oil is to commence at Bert McDonald's farm, Meadowville, Pictou County, N. S., the latter part of April. Pictou and Stellarton men are the promoters. A hole was sunk in the same vicinity some years ago, but was eventually abandoned.

At this month's meeting at Sydney, of the Cape Breton branch of the Engineering Institute of Canada, S. C. Mifflen, A.M.E.I.C., read a paper on the operation and equipment of the iron ore mines at Bell Island, Newfoundland. On the island five distinct seams of iron ore crop up, but only three are known to be workable. Within the past year the Dominion Iron and Steel Co., put in commission a turbo-electric power station of over 3,000 horse power. The power house is built on the sea shore line and a pier for storing coal is built about it, the foundations being laid in 18 feet of water.

The Muscle Shoals Project

Courtesy of "Universal Engineer."

IN ALL the stirring annals of the awakening South, no one event stands out like the great industrial drama of Muscle Shoals. To this vast, rich, but backward Tennessee Valley—"the Dimple of the Universe," as the romantic natives call it—the World War brought sudden, sweeping changes. Over night, almost, Uncle Sam poured thousands of men and millions of money into this smiling, sleepy region; at Muscle Shoals, near Florence, Ala., giant power and nitrate plants were rushed to completion to make powder for fighting Germany. Prosperity—a flood of government money and fat payrolls fairly engulfed all northern Alabama. At Sheffield, men paid a dollar a night for the privilege of sitting in a chair to sleep and tales are told of bold brokers who felt so flush that they even staked houses and lots in poker games.

Then the armistice—and the cold gray dawn of the morning after. Smoke ceased belching from towering stacks, for Uncle Sam had built and worked the plant only as a war emergency. So wheels stopped humming, the army of workers trekked over the hill, and the ghostly silence of ruined Pompeii settled down on rows of empty houses, on stores, theatres and churches—boarded up like Coney Island in January.

Yet here to-day stands a plant of marvelous potentialities, shut down, not because the country is not hungry for its product, but merely because Congress financed its operation only for the period of the war. Time and again, too, in years past, the engineers and power experts of the nation have called attention to the vast hydro-electric possibilities of Muscle Shoals. There is more horse power going to waste here, it is said, than has yet been developed in all other southern water-power developments taken together. Next to Niagara, engineers say, there is nothing like it in all our country.

The one outstanding war-time project which should be continued as a peace-time undertaking—at the same time retaining all its wartime functions for public safety—is this enterprise at Muscle Shoals, says the American Farm Bureau Federation's investigating committee in a recent report. There is no problem of conservation more vital, the report adds, than that of preserving the fertility of our soil; those who dwell in cities are of course as much concerned in our food supply as those who actually grow the crops.

In May last a special committee from the Mississippi Valley Association, sent to investigate the Muscle Shoals project, recommended that $10,000,000 be appropriated by Congress to carry on construction of the partly finished work. Congress failed to do this, and lately Mr. Henry Ford has offered to buy the project from the Government. Because of the magnitude of the undertaking and its importance to the whole nation a brief sketch of what has already been done at Muscle Shoals may be interesting.

The Tennessee River at the Shoals, from which it is planned to take power to operate the nitrate plants, and for sale to other industries, is as large—at average flow—as the Ohio at Cincinnati or the Mississippi at Dubuque. The banks of the river are of such a height that a 100-foot head of water may be held without building any retaining walls or dies, except the dam itself.

The big dam, known as the Wilson Dam, is about one-third finished and one-half paid for; when complete, it will be 4,426 feet long, 160 feet wide at the base, and will be the largest single piece of monolithic concrete construction in the world. Its height from the original river bed to the bottom of the overflow gates is 80 feet, and to the roadway on top, 133 feet.

The pool formed by the dam will extend about 17 miles upstream, and the total amount of land flooded by the water will be about 9,000 acres. This area has been practically all bought and paid for by the Government.

Two sections of the great dam, one at the north bank and one in the centre of the river on an island, are partly completed. The foundation is laid for nearly all the rest of the dam, and excavations for the power plant have been made. Two locks for navigation purposes are also partly excavated, each with a lift of 45 feet and with dimensions adequate for the largest river craft.

A fully equipped nitrate plant, known as No. 2, which cost $69,000,000 and with a capacity of 110,000 tons per annum of ammonium nitrate, stands near by. This giant cyanamid process plant covers nearly 2,000 acres, and during the war it employed 20,000 men. It was just rushed to completion and was producing nitrate in just one year—during the war.

Near by stands what is said to be the largest steam power plant in America. It was built so that this nitrate plant No. 2 could begin production without waiting for the completion of the Wilson Dam, which was expected to take about three years. This great steam plant produces nearly as much electrical energy as any other steam plant ever built, and contains one steam turbine unit with electrical generators which generate 60,000 kilowatts or 80,000 horse power. In addition there is provision for a smaller unit capable of producing 40,000 horse power, or a total for the entire steam-power electric plant completed of 120,000 horse power—ample to operate the electric furnaces in another part of the plant.

The boiler room of this immense plant holds a battery of fifteen units, each rated at 15,000 horse power. It burns 1,500 tons of coal per day—but is so remarkably equipped with automatic stokers and other devices that ten or twelve men can easily operate the whole plant.

All told, Uncle Sam has spent on this project a total of about $105,000,000.

This amount, however, includes the cost of a nitrate factory known as Plant No. 1, near Sheffield, where the Haber process was employed, but which was given over largely to experiments.

Such, briefly, is the great Muscle Shoals project as it stands today. Peace has come, and in peace the lessons of war are forgotten; already we have forgotten that when the Great War started we had powder enough for less than three hours' fighting—and had to bring our nitrate all the way from Chile! But even in peace, every day adds its acreage to our growing area of worn-out, abandoned farms, farms which only artificial fertilizers can restore to speedy production. Let us see, then, what the completion of this dam might mean to American agriculture.

Though we are the richest nation on earth, in agriculture we have burnt the candle at both ends. At first we farmed only the best soil, or moved farther west, or grew content with smaller returns as farms began to wear out. Today however, our population is increasing twice as fast as our crop production—we simply must grow more food, or eat less! As long ago as 1898, Sir William Crookes, then president of the British Association for the Advancement of Science, pointed out that the world's food consumption was running beyond the capacity of the cultivated land producing it. The only way world starvation could be averted, he said, would be by the universal use of a bountiful supply of fertilizer containing that most valuable element, nitrogen.

Keeping The Soil Young

Every wise American farmer now knows that the fertility of his soil depends upon the phosphoric acid and potash, and in a greater measure, upon the nitrogen it contains.

But because in the beginning we had virgin fields and fertile lands in such abundance, we were careless in our farming methods; and today we find that we have robbed vast areas of once good farming land of that nitrogen which only centuries can restore by natural processes.

Plain as this fact is to everybody, we must yet confess that America, despite her wealth and progress, is at least fifteen years behind countries like Germany, Norway, Canada, France, and even Japan in the production of nitrogen fertilizers. Though we have paid Chile to date nearly $850,000,000 for nitrates, and though we have a wealth of water power and a host of electric furnaces, till very lately we had not made one pound of air nitrates for use on our hard-taxed soil. Of all great nations we, the poorest of all nitrogen paupers, are practically the only one which has not seized this beneficent gift of science—a gift that can save us from inadequate crops and ruinous food prices. Germany alone has built up an air nitrate industry with an annual output of millions of tons freeing her forever from dependence on Chile, insuring her bountiful food crops, powder in plenty when needed again, and even actually enabling her to export this product of the air and sell it for good money.

So, no matter who may finish the Muscle Shoals project, the day it starts making air-nitrates will be a red letter day in the annals of American agriculture. But it will be only a beginning—for even if developed to maximum capacity, this plant could hardly produce one-fifth of our actual needs. Georgia alone could use a million tons a year. Undoubtedly one of the greatest industries in all America, in the future, will be the production and distribution of artificial fertilizers: eventually our needs must become so imperative that perhaps the central government itself will be compelled, in order to save the nation from going hungry, to take control of the fertilizer trade to develop other power plants like the one at Muscle Shoals.

You can visualize the importance of nitrate to this nation when you stop to reflect that our average corn crops takes from our soil about 3,000,000,000 pounds of nitrogen; that a 15,000,000 bale of cotton crop uses up 500,000,000 pounds of nitrogen; that every year, all our crops together probably use up 6,000,000,000 pounds! Of course the alchemy of nature is always at work, restoring this lost nitrogen, but it does not work fast enough to keep pace with the constant needs of growing crops.

Then, too, with enough cheap power we might free our farmers from enslavement to the German Potash Trust. Under the whole Allegheny Range, geologists tell us, there lies a deposit of "Georgia shale," so named from the enormous deposits in northwest Georgia, which run from 8 to 12 per cent. in insoluble potash. By electric furnace treatment the potash in this shale becomes soluble; so we might in time either free ourselves entirely from dependence on Germany or at least force down the arbitrary high prices now charged by the German Syndicate.

A Fortunate Location

As for the third element in a complete fertilizer, phosphoric acid, this is also now obtainable by breaking down phosphate rock in electric furnaces, instead of by the less practicable method of using sulphuric acid. Fortuitously, too, one of the largest phosphate rock deposits in the United States lies adjacent to Muscle Shoals, at Mount Pleasant, Tenn.

It is hard for the average man to understand how anybody, even a sleight-of-hand performer, can take a hatful of air and pull an ounce of nitrogen out of it. It is a trifle easier to grasp, maybe, after you've been through the air-nitrate plant about six times and had it all demonstrated to you, but even then you keep wondering how the first fellow ever came to think of it. One guess is that he reasoned backwards—back to the simple peasant habit of "plowing under" clover or bean vines to "rest" a tired farm, simply nature's way of fixing atmospheric nitrogen by taking it out of the air and putting it in the soil in tubercules on the roots of legumes. This is just what man now does, by the use of machines and the power of chemistry.

And whether you want air nitrates to make gun-powder or to fertilize your potato patch, their process of manufacture is the same.

For ninety years or since 1831, both Alabama and Uncle Sam have been spending money on locks and canals along the Muscle Shoals stretch of the Tennessee River. Just now, however, all navigation is blocked here by the partly finished dam. When complete, the vast inland lake created by the dam will enable the largest river craft to pass easily over the inundated shoals; great locks will pass such craft through the dam, and then the vast rich basin of the Tennessee, with its coal, limestone, coke, iron, lumber and farm products, will be tied up with the 13,000-mile network of navigable inland waters of the Mississippi basin.

Army engineers have estimated that the cost of the improvement at Muscle Shoals, properly chargeable to navigation should be about eight and a half millions.

They say that the improvement of the river for navigation alone would cost more than its present traffic would justify; but when coupled with an industrial development that means cheaper fertilizer, cheaper electric power for sale, a big plant on which the Government might depend for nitrates in case of war, the river improvement seems to be very much worth while.

This, briefly, is the plant Mr. Ford has offered to buy. Should he do so, it will be perhaps the largest transaction of its kind ever closed. Here is what he offers:

To lease water power equipment for 100 years, at a price that will pay the Government 6 per cent on the estimated cost of completing the two dams, or $28,000,000.

To pay the Government annually a sum that will in 100 years retire nearly its entire war-time investment on water power.

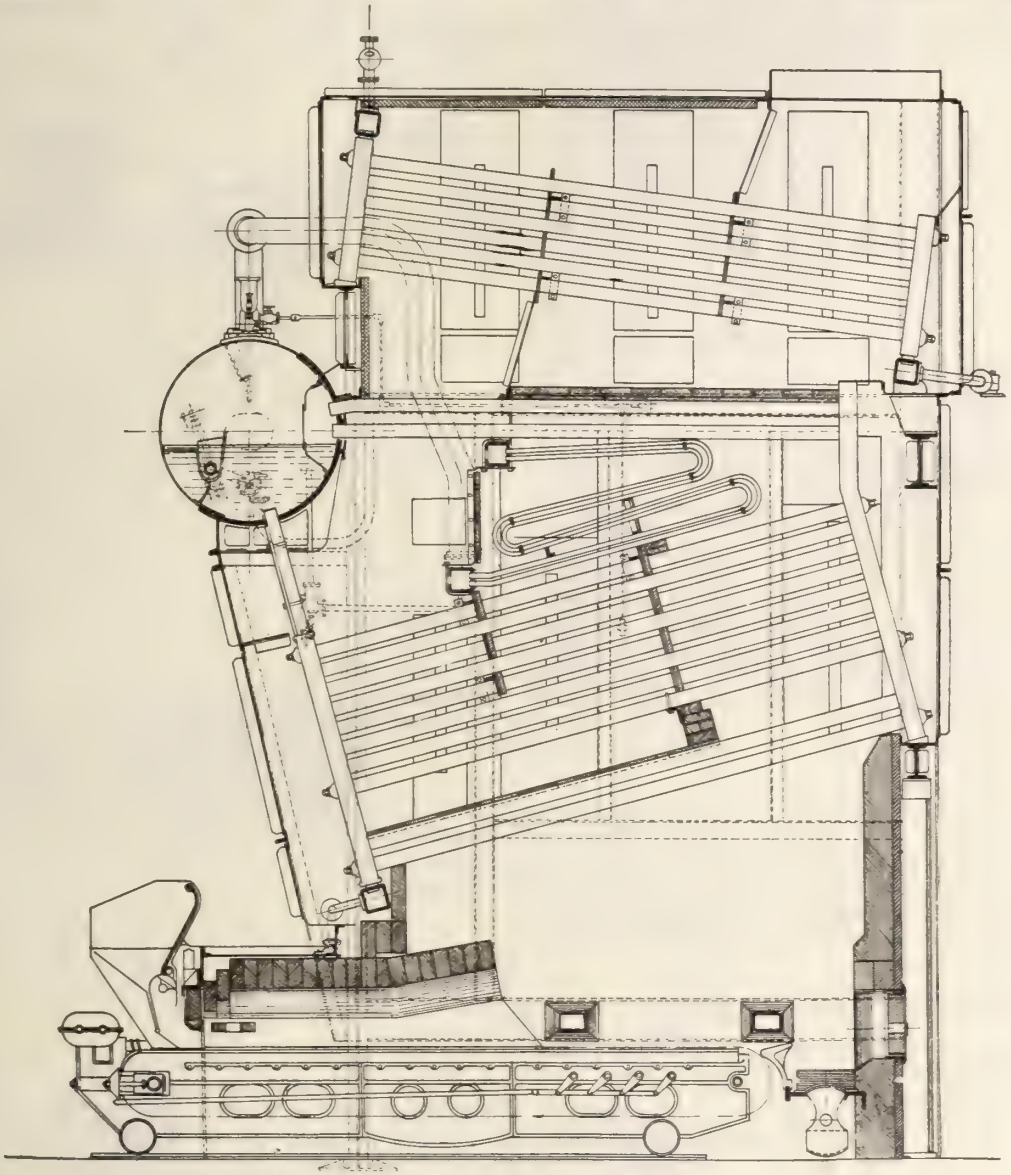
To buy nitrate plants and other property for $5,000,000 cash.

To pay the estimated cost of upkeep and repairs on the dam and water-power equipment and furnish free power to operate the navigation locks.

To make nitrates in Plant No. 2, to conduct researches for keeping the plant up to date in developing cheaper fertilizer producing methods, and to limit fertilizer profits to 8 per cent.

Such is the story of the power and value of falling waters at Muscle Shoals, Niagara of the South. Nowhere, perhaps, has Nature set her stage more favorably for a vast, industrial drama. I have shot wild guineas amid the ruins of Babylon, where Sir William Wilcocks dammed the Euphrates to water the farms of Mesopotamia; I've fished for bass above the giant Roosevelt Dam and I know the Valley of the Nile, with its modern miracle at Assuan. But I know no other power or irrigation site, where the wealth and strength of nature seems so peculiarly assembled and ready for man's use, as here at Muscles Shoals.

High Efficiency Boilers



(Cut lent by courtesy of Eng. Institute of Canada.)

MARINE BOILER---ADAPTED FOR LAND PURPOSES---EQUIPPED WITH CHAIN GRATE STOKER, SUPERHEATER and SUPERPOSED ECONOMISER

The construction embodies the same well-known principles as the standard type; freedom of circulation and economy when forcing being important factors of both designs. It has the added advantage that a large amount of boiler horse-power occupies a relatively small floor space.

This type is particularly useful for central stations and other plants where turbines are used and the working pressure is high. It operates economically under the special conditions of variable loads with heavy peaks. A big increase in efficiency over smaller boilers is effected through a reduction of radiation and other losses.

The individual Economiser superposed on this boiler increases the efficiency, reduces the flue gas temperature and effects considerable saving in space and of many of the losses incident to the use of separate economisers.

TORONTO OFFICE: BANK OF HAMILTON BUILDING

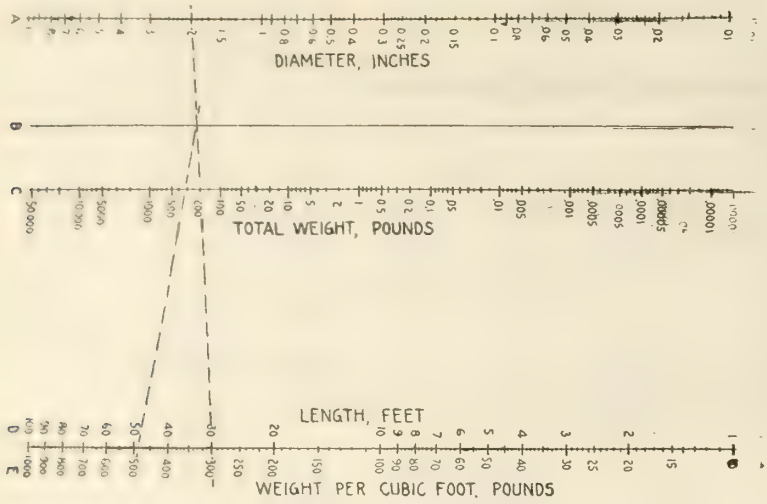
WEIGHTS OF METAL BARS

By W. F. Shraphorst

The accompanying chart provides a convenient method of determining the weights of solid or hollow metal bars of ordinary dimensions. By means of a straight edge placed across the chart as shown by the dotted lines, the weight may be easily found. The chart shows the result for a bar of mild steel 2 in. in dia. and 30 ft. long. The table herewith shows the weight of mild steel to be 487 lb. per cu. ft. By connecting the 2 in. column A with the 30 in. column D, and working back from the intersection on line B over the 487 in. column E, the point where the straightedge cuts the column G will be the desired weight; in this case 320 lbs. By calculation the weight is found to be 318 lbs.

The weights of common metals mostly used in industry are as follows:

Aluminum	lbs. per cu. ft.	165
Brass		534
Copper		556
Wrought iron		485
Lead		710
Nickel		537
Mild Steel		487



The chart may be used vice-versa if desired. If it is required to know the length of bar that will weigh a certain number of pounds the reverse process would be necessary.

For hollow bars the same method would be followed, calculating the inner and outer diameters and deducting the former from the latter.

Payne Deane Ltd., New York, have issued a bulletin describing their remote control and remote control indicators for gate valves for water systems. The bulletin is No. 43A.

PIPE THREADING MACHINE

A 12 in. threading and cutting machine that can be equipped for threading oil well casing and hydraulic pipe has been placed on the market. The normal range is from 4 in. to 12 in., but may be adapted to cut pipe 2½ in. in dia. The range is accomplished by means of two die heads, each head having only the one set of chasers. The die head or carriage may be moved either by hand or power, one operating lever controlling the traverse in either direction. Automatic safety stops are provided for the carriage travel. The reaming tool is quickly set to position and locked with a lever. The reamer is fed to the pipe by rotating the cutting off feed hand wheel in a counter clock-wise direction.

The machine has a single pulley drive. The variations of speeds, eight in number, are obtained in the speed box, located under the main spindle, by shifting levers on the side of the gear box. The machine is started and stopped through a friction clutch by either one of two levers located at the extreme ends of the head stock. This enables the operator to start or stop the machine when threading or when fitting up flanges. A lever is located midway between the starting and stopping levers for reversing the machine. The chucks for gripping the pipe have three jaws. These jaws are geared and have universal adjustment. They are also self-centering to the pipe. The rear chuck is equipped with flange grips for fitting up flanges.

Is made by the Landis Machine Co., Waynesboro, Pa.

STILL IMPROVING THE LOCOMOTIVE

The locomotive, now about a hundred years old, was a British invention; and to-day engineers continue to introduce improvements in its design. Over forty years ago a device known as the "exhaust steam injector" was brought out. Its purpose is to use the power in the exhaust steam from the cylinders to force water into the boiler. The first injector of this kind was able to do its work against a pressure in the boiler of 70 lbs. per square inch. Later it was improved so as to feed at 120 lbs., and for higher pressures it was necessary to call in the aid of live steam from the boiler itself. Lately, however, a British firm invented a modification by means of which the injector can work against a pressure of 150 lbs. per square inch with one pound of exhaust pressure, thus effecting a great economy in live steam. This improvement is due to the use of an additional nozzle which brings the steam into more effective contact with the stream of water. In practice the amount of live steam required when this new device is fitted is nearly half what it was formerly and amounts to only 2½ per cent. of the total steam produced by the boiler.

The development of the power plant of Manitoba Power Co., it was stated at the annual meeting held in Winnipeg, is progressing very satisfactorily, over 500 men being employed on the works. The transmission line from the Winnipeg Electric Company's hydro-electric plant to the work, a distance of 17 miles, has been completed, and power is now being used in connection with the construction work. The orders for the hydraulic and electrical equipment have been placed. The turbines are being made by the Dominion Engineering Co. at Lachine, Que., and the generators by the Canadian General Electric Co. The switchboard and the Kingsbury bearings are being made by the Westinghouse Co.

The city of Sault Ste. Marie, Ont., is having plans prepared for the installation of two gasoline engines for direct connection to present pumps in the pumping station. Cost to be about $20,000.

HINTS TO BUYERS

Kingsbury Thrust Bearings

Made in Canada

Our pivoted-block Thrust Bearings are a complete solution of all thrust-bearing problems in hydro-electric units, steam turbines, ships' propeller shafts, centrifugal pumps, and similar work involving heavy loads and high or low speed.

Maximum Durability and Reliability.
Lowest possible Friction.
No limit to loads or speeds.
Protected by numerous Canadian Patents. Complete manufacturing facilities in Canada, insuring prompt deliveries and service.
Send for Catalogue.

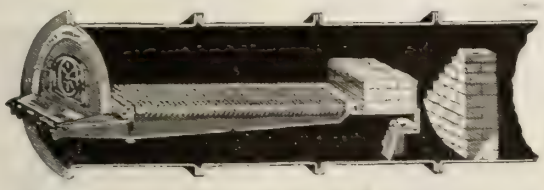
In the last issue we described a successful test with "Hog Fuel" in the

Turbine Furnaces



There is Hog Fuel— and Hog Fuel

Some contains very little moisture, but cottonwood contains 66 2/3 per cent. as an average, and sometimes more.

At the plant of the Laminated Materials, Ltd., the home of "LAMATCO" Wall Board, New Westminster, two boilers were required to burn this fuel to keep up steam with the assistance of $400.00 worth of purchased fuel.

A set of Turbine Furnaces was installed, with the result that one boiler, **without** the use of purchased fuel, is all that is necessary.

Manufactured by
The Turbine Furnace Co., Ltd., London, England

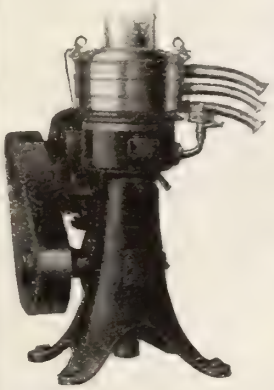
Agents for Canada:

PERCY A. GOEPEL
525 Pender Street West, Vancouver, B.C.

Stop Wasting Oil

The De Laval Oil Purifier returns to service lubricating oil or transformer oil which would otherwise be thrown out. Better still, its continued use constantly maintains the efficiency of such oils.

The De Laval does its work instantaneously, thoroughly and economically by centrifugal force. It is the modern method of making turbines and Diesels give longer and better service, and of prolonging the life of the oil used to lubricate them. It is the far more economical method of maintaining the dielectric strength of transformer oil.



No matter which of these tasks you give a De Laval—you can use the same machine for both — you have absolute assurance that the work is being done better and more economically.

Write for Bulletin No. 105

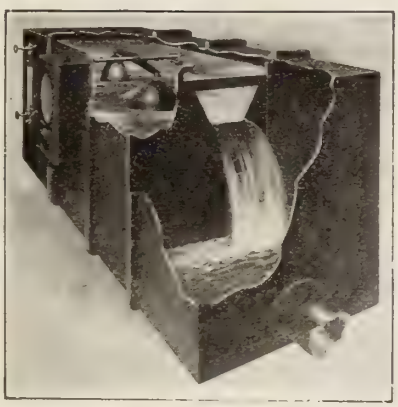
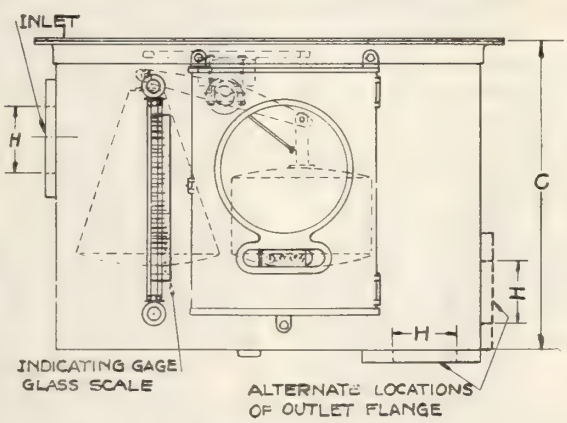
The Simplest Construction Always Proves The Most Accurate!





THE BAILEY WEIR METER

—FOR ACCURATELY MEASURING ALL LIQUIDS

Accurate and long lasting because free from troubles and inaccuracies arising from the use of cams, springs, flexible connections, racks, gears, roller guides, etc. Every plant needs it for measuring feed water, condensate, and other liquids.

The Bailey Weir Meter indicates, records and totalizes the flow of liquids. A glance at the diagram above shows its remarkable simplicity. Can be also fitted for temperature recording. 12″ diameter uniformly graduated charts are used. Ask for bulletin No. 60.

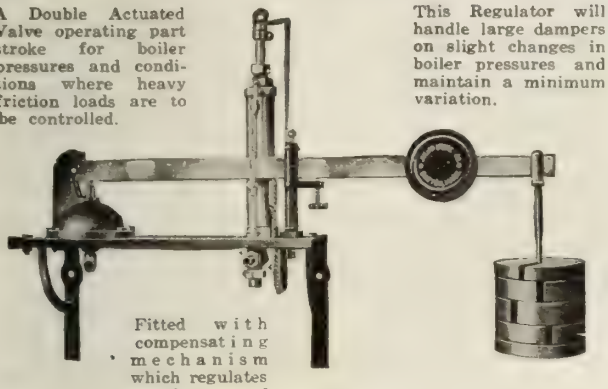
D'ESTE

Hydraulic Damper Regulator

A Double Actuated Valve operating part stroke for boiler pressures and conditions where heavy friction loads are to be controlled.

This Regulator will handle large dampers on slight changes in boiler pressures and maintain a minimum variation.



Fitted with compensating mechanism which regulates opening and closing.

Our Catalogue No. 50 of CURTIS ENGINEERING SPECIALTIES sent on application.

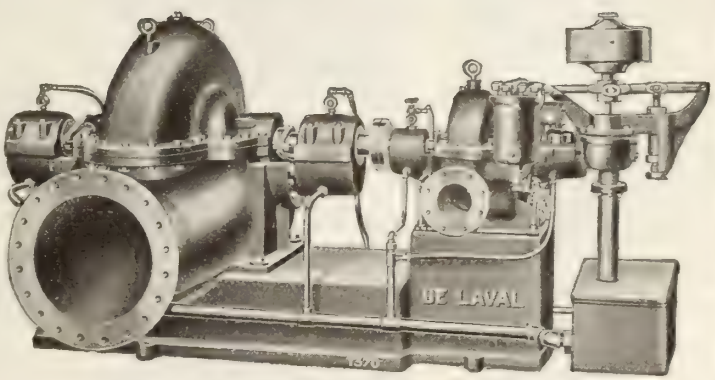
Turbine-Driven Blowers
Must be Rugged

THE DE LAVAL TURBINE-DRIVEN BLOWER unit shown is designed for gas plant work. It serves however, to illustrate the care taken in designing De Laval apparatus to insure continuous, satisfactory service. Note the heavy construction of all parts, including the blower casing, also the forced lubrication with sight feed and the powerful and accurate speed governor, all features contributing to reliability in operation.

The same features are apparent in the design of all other De Laval apparatus, including turbine-driven generators, centrifugal pumps, blowers and compressors, speed-reducing gears, geared turbines for rope and belt drive, etc.

State class of apparatus in which you are interested and appropriate literature with special data will be supplied. Ask for Catalog F100.



De Laval velocity stage turbine driving single stage gas blower; 11,000 cu. ft. of free air per min. against 33 in. water column at 3,600 R.P.M.

Power House advertisers are at your service. Many engineers have been enabled to qualify for better positions, have been instrumental in securing the installation of more efficient equipment, have been of exceptional service to the firm they are engaged by, **because** of their superior knowledge of equipment, which knowledge was largely attained by being conversant with the latest advertised equipment, found in **Power House.**

PUMPS

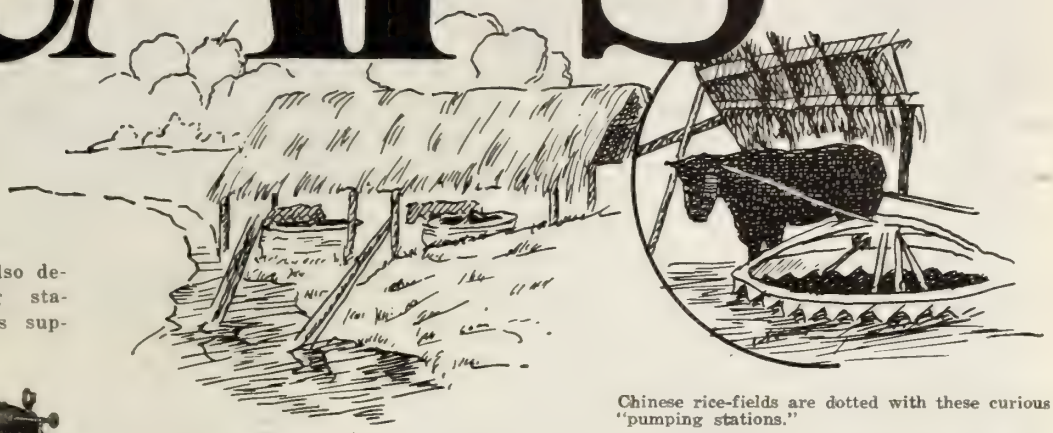
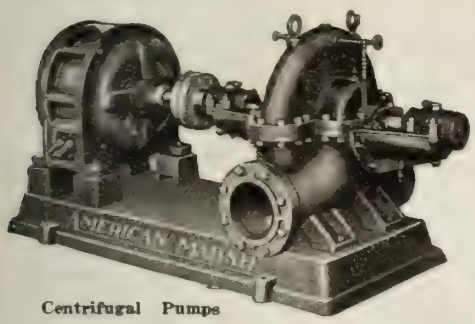
Because his rice-fields were always calling for water, the Chinaman was forced to become something of an engineer. Not only did he invent a number of different kinds of pumps, but he also developed primitive "pumping stations." Oxen and cog-wheels supplied the necessary power.



Chinese rice-fields are dotted with these curious "pumping stations."



Centrifugal Pumps

Wherever — to-day — you run across difficult pumping problems, you will find American-Marsh Pumps on the job. Our Centrifugal Pumps (as is the case with all American-Marsh Pumps) are simple, reliable and efficient.

SUPERHEAT—

A Cure for Waste

Save **one** shovel of coal in **five** by applying

ELESCO SUPERHEATERS

Reduce condensation in your steam lines—it is a needless waste; increase the entire efficiency of your plant by **Superheating** it.

In a plant operating under a load of 5,000 KW, 24 hours a day, 50 carloads of coal are saved a year. At $6.00 a ton, ELESCO Superheaters would save $12,600.

May our engineers study your operating conditions and report what superheating will mean in your plant?

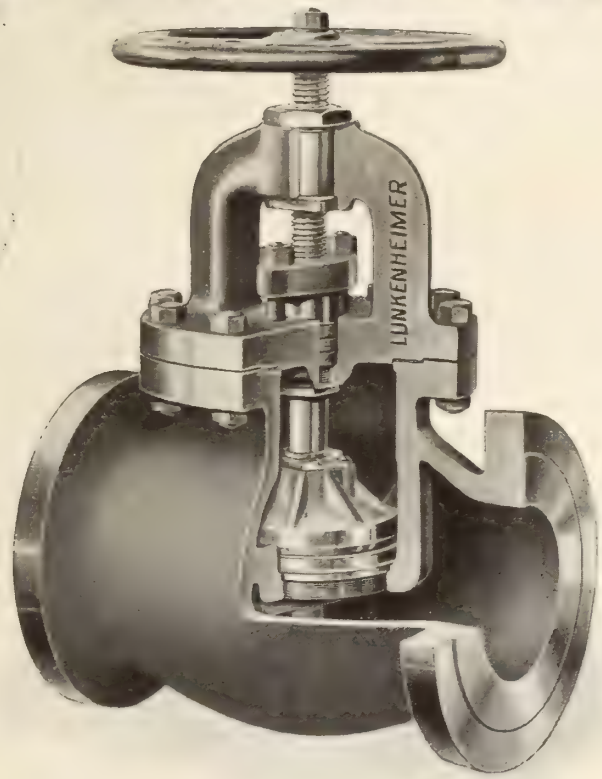
LUNKENHEIMER

Globe, Angle, Cross and Check Valves



Extra Heavy, Fig. 884.

Standard, Fig. 1123.

Service economy—long life with a minimum cost for upkeep—is the dominant factor which has led to the selection of LUNKENHEIMER Iron Body Valves as "standard equipment" in many leading plants. Their success in service is the direct result of the combination of correct design with proper materials and the Lunkenheimer method of manufacture.

LUNKENHEIMER "Valve-iron" and Lunkenheimer "Valve-bronze" are formulated especially for valve service and the Lunkenheimer method of manufacture insures dependable results under prescribed operating conditions.

The line embraces a variety of types and sizes in Standard and Extra Heavy Patterns for pressures up to 125 and 250 pounds respectively, whose performance and durability fully measure up to the Lunkenheimer high quality standard.

There is a LUNKENHEIMER Distributor in every commercial center ready to give prompt service. Specify LUNKENHEIMER Iron Body Valves and insist on getting what you specify.

Check Valve

Globe Valve

Morrison Steam Goods

Beaver Valves

—Supreme For High Pressure Service

TO successfully meet the requirements of high pressure steam something better than the ordinary globe or angle valve is required. Several basic constructional features of "Beaver" valves satisfactorily adapt them for this service.

The improved joint between body and yoke and machined faces of the double spigot prevent any possibility of gasket blowing out. There are large areas through body and seat—free flow of steam or water is facilitated. Minimum space occupied; renewable seats and other features recommend "Beaver" valves for the hardest service.

They are designed for a working steam pressure up to 250 lbs. Built in Globe, Angle, Cross and Check patterns.

To Save Real Money in Your Boiler Room use the

NATIONAL HAND FIRED STOKER

The heavy labor of firing is eliminated and low grade labor with very little training can get results all the time, day in and day out, that experienced stokers can only get part of the time. Any grade of fuel can be used—smoke is eliminated with all grades of coal—no fuel in the combustion chambers—no ashes in the flues—increased boiler capacity—and much lower labor cost are National advantages. The banks of Pushers, operated by rods from the front of the furnace keep the fuel moving downward until the dump plates are reached—insuring just about PERFECT COMBUSTION and a degree of efficiency and economy in your Boiler room that will delight you.

The National Hand Fired Stoker is applicable to old or new installations. We build it in St Catharines. Let us send you full particulars and prices.

Engineering & Machine Works of Canada, Limited

Eastern Sales Offices: Hall Machinery Co., Sherbrooke, and Birks Bldg., Montreal

"Burn All"

Will You Reduce Your Fuel Expenses?

A number of the largest manufacturing concerns in Canada were asked this same question. Their answer was to instruct their experts to report as to the merits or demerits of our claim that

For Grates Write Sexton

THE NONPAREIL GRATES

Cut 10% or more off Fuel Expenses

After exhaustive investigation, these experts (without exception) placed the stamp of their approval on Nonpareil Shaking and Dumping Grates.

These Grates give complete combustion of every pound of coal—65% air space, 95% underdraft, low grade fuel.

You are at liberty to order a set of Nonpareil Grates and test them out FREE OF CHARGE. We guarantee a saving of **at least** 10% on your fuel consumption. If they fail in any way, ship them back to us—we pay the freight. You will agree that this is a reasonable and fair offer—then why hesitate?

Manufactured by

THE W. R. SEXTON BOILER SETTING CO.

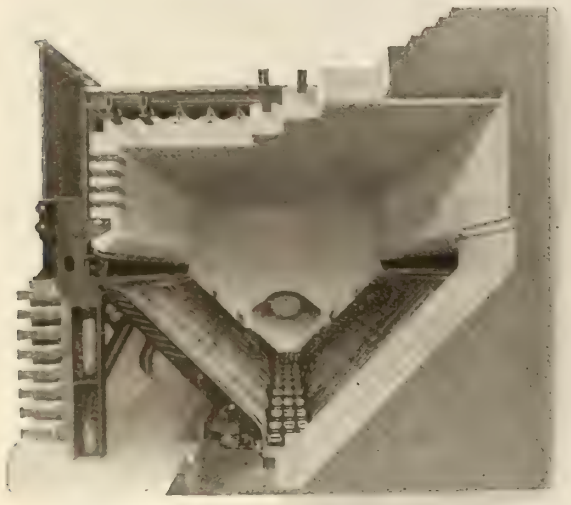
Established 1900—Phones: College 682; Junction 2765W.

Renewals and Repairs made for all kinds of Shaking and Dumping Grates for all sizes of Boilers

DETROIT "V" TYPE STOKERS



Detroit "V" Type Stoker, Heavy Duty Type, with Detrick Flat Suspended Arch (rear view)

Quarter-section, Radial Stoker and Arch Stoker, showing Coal Magazine and arch support, with removable tuyeres and protecting brick

The special Fire Brick shapes furnished with Detroit Stokers are made from the highest quality refractory material, molded by hand in steel molds and repressed to insure uniformity and durability.

Secure Complete Combustion

You have gone to large expense in installing up-to-date equipment in your plant, to insure economy in operation. How much of the potential energy in your fuel are you actually utilizing in producing steam?

Very much less than you could or should if your boilers are hand fired!

Compare some of the advantages of Detroit "V" Type Stokers over uneconomical hand firing!

A. Hand firing is intermittent, its evenness and effectiveness depending upon the individual skill and attentiveness of the fireman. With Detroit "V" Type Stokers the human factor is eliminated; firing is continuous and uniformly even, assuring high combustion efficiency.

B. With hand firing, one fireman can at the best take care of 250 to 500 H. P. of boilers, whereas with Detroit Stokers the same man can handle 2000 to 3000 H. P. thus reducing labor costs 75 per cent.

C. Detroit "V" Type Stokers burn cheaper grades of fuel than can be used to advantage with hand firing, thus paying for their cost several times over each year.

In addition consider the advantages of control of air admission, thorough automatic cleaning of fires, and smokeless operation, resulting from a Detroit Stoker installation.

Detroit Stokers today represent the best fruits of a practical knowledge gained in the Company's twenty years of successful stoker building, and the recent important developments in the science of combustion. There is a type for every purpose—"V" Type overfeed for natural draft—Single Retort Underfeed for boilers developing up to 300 to 400 H. P.—Multiple Retort Underfeed for large installations.

Take the first step toward reducing boiler room costs. Write for full information.

Branches in all Cities

Each brick independently supported and can be Replaced without disturbing the adjoining brick

Suspended Arch Troubles Eliminated By the M. I. W. Suspended Arch

The M. I. W. suspended arch has been developed with the idea of eliminating defects found in arches of this character and contains a number of important features not found in any other arch manufactured.

This suspended arch can be constructed in almost any form desired to meet special requirements.

This design eliminates all expansion strains, cracking and spalling of brick due to expansion and pressure of adjoining brick.

COMPANY Limited
Ontario

Factory & Main Office Illinois Watch Case Company Elgin, Ill.

Saving Thousands of Pounds of Coal per Day

Increasing their steam output and reducing the cost of steam per thousand pounds, the Illinois Watch Case Company, Elgin, Illinois, has demonstrated that modern factory standards pay big dividends when applied to a boiler room.

This well known company makes watch cases on a quantity production basis. Every modern test and standard of manufacturing equipment is in use in the factory.

These same standards are applied to their boiler room—the steam factory department.

Green Chain Grate Stokers are used. The results are expressed in Mr. I. B. Eppenstein's letter of Aug. 17, 1921.

> "Prior to installing Green Chain Grate Stokers we consumed approximately 12 tons of coal per day, and furnished power for only a small portion of our plant. The balance of the power being purchased from a public service company.
>
> "Since the installation of Green Chain Grates in our new power plant, we supply power to the entire factory, no power at all being purchased, and consume approximately 10 tons of coal per day.
>
> "Our saving on coal amounts to about $184.60 per month."

Green Chain Grate Stokers maintain a common sense balance of Efficiency, Capacity and Maintenance. The result is steam produced at the lowest unit cost.

Green Steam Jet Ash Conveyors and Cast-Iron Hoppers provide a clean, quick and economical method of ash removal, transfer and storage.

Green Engineers will be glad to show you how to apply modern factory standards to your boiler room. A letter to Dept. X will incur no obligation on your part and literature covering Green products will be mailed to you.

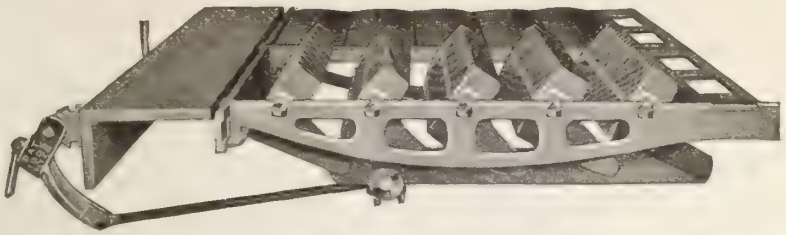
Are You Open to Conviction?

Every progressive business man is usually willing to lend an ear to reason. Consider this:. you can save several tons of coal each month by changing your ordinarily constructed fire grates for Cyclone Grates, and the money you will save through fuel economy will in a reasonably short time pay for the installation.



CYCLONE Grates

The scientific design of Cyclone Grates permits the use of low grade fuel with good results—60% air space, 90% underdraft. The jarring, shaking movement of the grates sifts ALL the ashes through and leaves ALL the good fuel to be burned. No clinkers! No waste!

To bring trade back to normal

We have decided to sell our grates at the lowest possible price—regardless of any profit to ourselves. This is your opportunity. **Buy now!**

MACLEAN STOKERS

IN EVERY plant where the MacLean Stoker has been installed the result has been a great saving both in labor and fuel. Working automatically, it feeds the fire just the right amount of coal, varying the feed in accordance to varying demands for steam. In this way a constantly uniform steam pressure is maintained regardless of sudden load fluctuations.

The MacLean Stoker burns all classes of bituminous coal. There are no siftings of unburned coal to the ashpit because there are no grates.

The MacLean Stoker is easy to instal—easy to operate—and is adaptable to any kind of boiler plant, large or small. The actual upkeep is negligible owing to simplicity of construction and the fact that no moving parts are in contact with the fire.

May we estimate the saving to be made in your plant? You are under no obligation to purchase.

"Jenkins Valves Only"

says Pilkington's Chief Engineer

Fig. 106
JENKINS BRASS GLOBE VALVE
Standard Pattern

Knowing valves and valve requirements he prefers Jenkins Diamond-Marked Valves because he has seen them in service, year in, year out —ever dependable and free from trouble.

In big manufacturing plants like that pictured above, dependable valves are all important.

That is why Canada's leading engineers regard the installation of Jenkins Valves as a paying investment. Genuine Jenkins pay for themselves in savings of time, labor and replacement charges.

There's a Jenkins Valve for every requirement of Power Plant, Industrial and Domestic service. The complete line is shown in Catalog No. 8.

The Dunham Return Pump
Type R. L. P.

HANDLING CONDENSATE With the DUNHAM RETURN PUMP

This new Dunham Return Pump is designed to automatically pump condensate from heating systems, or process work, back to boiler, heater, hot well or other storage. It is an automatic, electric driven, centrifugal pump, stopped and started from a float switch.

The waste of condensate from heating systems where returns are below the boiler water line can be entirely eliminated by the use of the Dunham Return Pump. The condensation from the heating system is returned to the boiler as it accumulates, resulting in improved heating and a saving of fuel.

Dunham Return Pumps are absolutely automatic in action and operate without attention, day or night. There are none of the difficulties caused by low pressure steam pumps when fires are banked for the night.

Full particulars will be sent upon request.

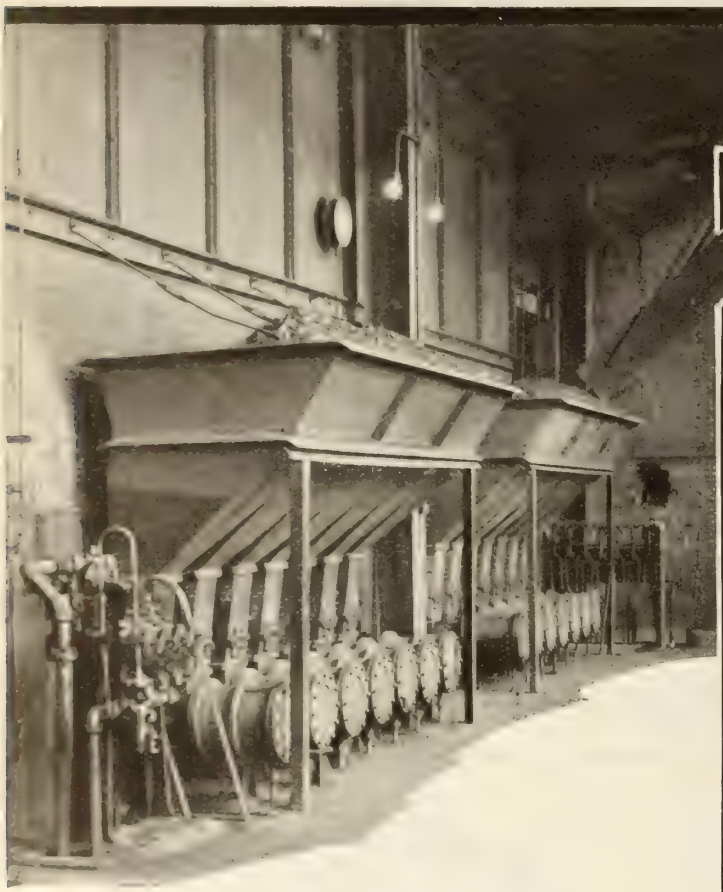
JONES STOKERS



POWER interruptions will not, and should not, be tolerated in modern plants. That is why Jones Stokers are favorites for plants of practically every size. Their rugged simplicity makes shutdowns for repairs next to impossible. Fuel and air are automatically controlled; little attendant labor is required.

In the "A-C" (Automatic-Cleaning) type, fires are automatically cleaned.

Retorts may be individually controlled—an exclusive feature.

Clinkers do not form on bridge or side walls.

The under-feed principle of combustion (originated in Jones Stokers) insures maximum economy of fuel at all loads.

These, and other distinctive features that make the Jones Stoker "pay for itself—then pay dividends," are covered by the new catalog.

PISTON AND PLUNGER TYPE

The Value of Uniformity

The time wasted in changing parts of a pump is an expensive item that does nothing but add to general O.H. charges. This expense is reduced to a minimum in the McGowan Duplex.

These pumps are built to **uniform specifications of the highest standard** with all parts readily interchangeable; in fact, the entire working parts could be replaced in less than an hour, if it were necessary.

Considering the late improvements adapted in our Standard Duplex Steam and Power driven pumps, and the consistent high quality of material and workmanship for which they have long been noted, the price is remarkably low.

We have full line of patterns for direct acting steam pumps and belted or direct connected power pumps.

We shall be pleased to figure on your pumping requirements.

CoKal Hopper Feed Chainless Stokers

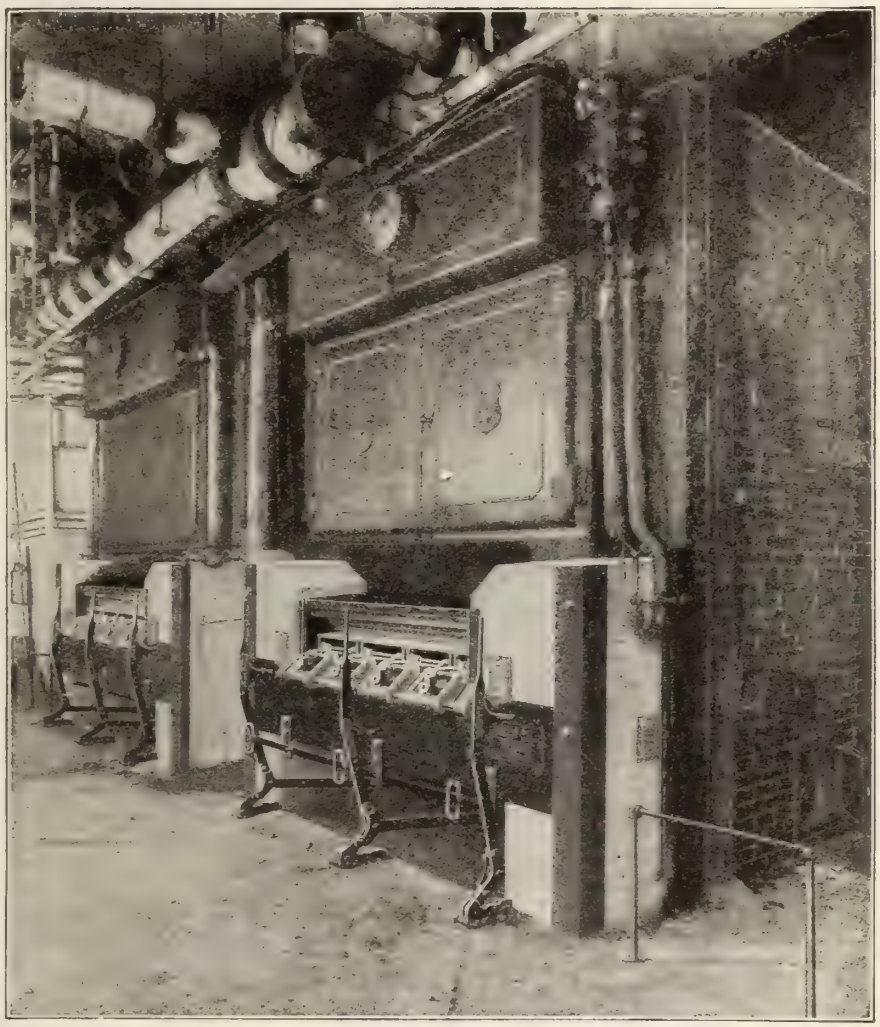
Self Cleaning—Hand Operated

Always Ready for the Peak Load

THE CoKal Hopper Feed Hand Stoker keeps a supply of hot incandescent coke ready for immediate distribution, and permits the recharging of the furnace without opening any fire doors to admit excess air.

Movable feeder blocks control the fuel feed of the hopper, causing the coal to be admitted when and where required. These blocks close the communication between furnace and hopper. They also accelerate the fuel feed when necessary to speed up.

The CoKal Hopper Feed Hand Stoker requires less space for coking, giving more effective stoker area and making it possible to operate at 150% to 300% of rating with suitable draft conditions.



CoKal is Chainless and Crossfeed

A multiple series of intermeshing fingers are so placed as to distribute the fuel both sidewise and lengthwise, closing any holes in the fire and insuring a uniform fuel bed.

Burns cheaper fuel and eliminates smoke. Fires always clean—high efficiency assured. Costs less than automatic stokers and gives the same results. The CoKal stoker is the best hand stoker built. Don't measure hand stokers by the price—rather get dependable performance.

If interested fill in the attached and forward:

We burn.....tons of.....coal annually.

We operate.....hours per day. We have.....boilers.

The Principal Types of Mechanical Stokers

While the Number of Different Makes of Mechanical Stoker is Legion, They All Conform to One of Three General Types, for the Larger Units. For Small Units Other Types Exist

THERE is no doubt of the general acceptance of the principle of the mechanical stoker, and its manufacture has become practically a special industry. There are a large number of makes on the market, differing in detail, but practically confined to three well-known types.

These are the overfeed, the underfeed and the chain grate stokers. For smaller boilers, up to 200 h.p., there have been developed a variety of stokers, including the sprinkling or throwing types, and those equipped with movable bars for shaking the fire bed, and in some cases dumping the clinks and ash, which are operated by means of levers worked by the firemen. The tendency to-day is to get away from hand stoking whenever possible, even when the change does not effect a saving of labor.

The great objection to hand stoking, even supposing the fireman is a master of his craft, is the necessity for continually opening the fire doors, and the length of time they must be kept open while the fuel is being delivered to the furnace. The doors have to be opened up to lift the fire from the bars and prevent the formation of clinker, and after the lifting has been done, the fuel has to be raked over on the top to preserve its even thickness. Naturally every time these operations are performed, cold air rushes into the furnace, with its accompanying loss of heat, and fuel. There are also sometimes serious mechanical defects induced by the entrance of cold air while the doors are open.

A further drawback to hand firing, is the limitation of the size of grates, that is as far as their length is concerned, for a man cannot handle a fire which is more than from 5½ to 6 feet long, especially when the cleaning time comes. This cleaning of fires is one of the hardest things that a fireman has to contend with, and is at best a long process, attended with inconvenience and loss, and often in a plant that is hard-pushed, a considerable drop in steam pressure results. With mechanical stokers all these disabilities are removed and a means provided by which coal can be fed at practically any required rate, and with the help of forced draft, burned at high rates per square foot of grate surface per hour, with much higher efficiency than is possible under hand conditions. It is of course quite possible to have very low efficiency with mechanical stokers if they are not properly regulated, and to this extent they require the guidance of human brains. Given this modicum of attention, they will deliver the goods both from the point of view of high rating and high efficiency of combustion.

Choice of Stoker

The question of whether to use mechanical stokers or hand firing is settled at once by the size of the boiler installation. For anything under 200 h. p. it becomes a question of very careful figuring to determine whether the investment will be justified by the saving in fuel, because it must be remembered that there can be no labor saving on a small installation. However, as mentioned before, for this type of plant, there is available the type of stoker that can be installed at low cost, such as the sprinkler, or one of the various types of moving, or moving and dumping grate bars. These will justify themselves on the ground of fuel saved, even if there is no labor saving. In cases where the total installation may be as much as 600 to 700 h. p., but the units of small size, as in the case of the horizontal boiler, these semi-automatic types are useful.

When it is a large plant, or a plant with large units, the choice of type of stoker will be governed by the kind of fuel available, and the rating to be developed by the boiler. Where the load is of a steady nature, and the boilers are to be operated at about their normal rating, a natural draught stoker is probably the most suitable. If the fuel is of a high volatile character, the chain grate stoker would be the best to use. Where high ratings are to be encountered, for varying periods, or where the boilers are to be run overrating all the time, a forced draft installation is indicated. For burning such fuels as anthracite slack in the very small grades available a chain grate stoker is very suitable. For bituminous coals with a moderate amount of volatile content, and high in fixed carbon a stoker of either underfeed or overfeed operation can be used. It is difficult to say definitely where the usefulness of one type ends and another begins, because lately all types of stokers have been adapted to burning all kinds of fuel. For instance, wood mill refuse has been burnt with very good results in conjunction with coal on underfeed stokers, and such fuel as tanbark with a high degree of moisture has been handled successfully on overfeed stokers. Western lignite, which is a low grade fuel, has been burnt and is being burnt on chain grate stokers.

Chain Grate Stokers

The chain grate consists essentially of a flexible steel chain conveyor, fixed on rollers at front and back of furnace, and driven by a small engine or motor through suitable gearing. The speed of the grate is made variable, either through a variable speed motor on the drive shaft, or a series of change gears on the stoker shaft itself. This variation of speed in the grate is accompanied by a variation of rate of combustion of the coal.

The fuel is fed from the containing hopper through a gate which in some cases has a fixed opening, and in others a variable opening to the grate. In order to produce ignition rapidly, an arch faced with a refractory brick is suspended over the grate, covering the part of the furnace which is outside the setting of the boiler. This refractory ensures the volatile gasses being thoroughly ignited and combustion carried out before the cooler surfaces of the tubes or boiler shell are met with, and the arch is usually known as the ignition arch on this account. The grate traveling along carries the burning carbon slowly under the reheating surfaces, and when the back of the furnace is reached there is nothing remaining but the incombustible. As the chain turns around over the back roller on its completion of the revolution, the unburnt residue is precipitated into the ashpit.

This point at the back end of the furnace has to be carefully designed so as to leave no space by which excess air could be drawn in over the grate. In some designs what is known as a water

back is fitted, this being a hollow casting through which the boiler water circulates. As the fuel is brought along by the grate to the end it is pressed against this water back. This compresses the top layer of the fuel while leaving a space for the ash to drop underneath, and thus makes an air seal. The water back also prevents the clinker adhering as it would to a hot brick face.

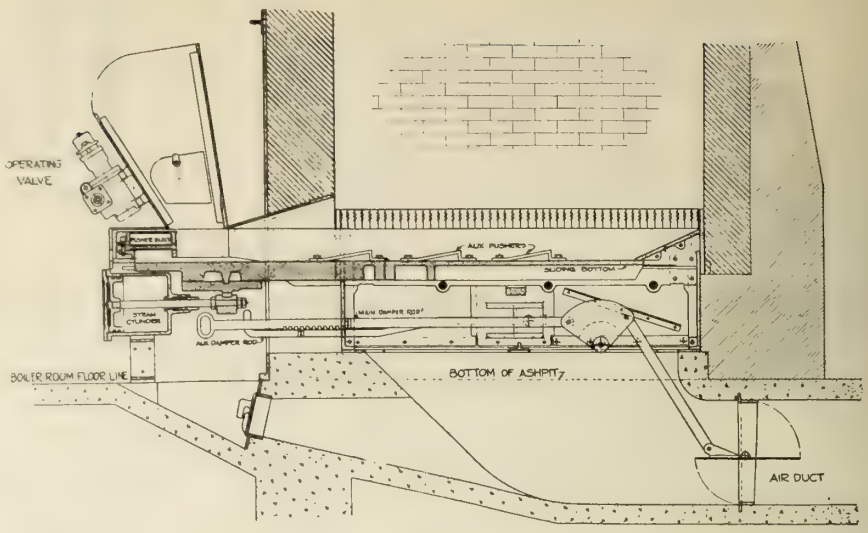
The action of the chain grate may be classified as progressive combustion, the volatile gases being first distilled and ignited by the heat of ignition arch, the air coming through the grate from underneath supplying the necessary oxygen to give complete combustion of the volatile matter and the solid carbon remaining on the grate. Rate of combustion can be varied by varying the speed of travel of the grate, which automatically increases the rate of combustion per square foot per hour.

We illustrate a number of the different types of chain grate stoker.

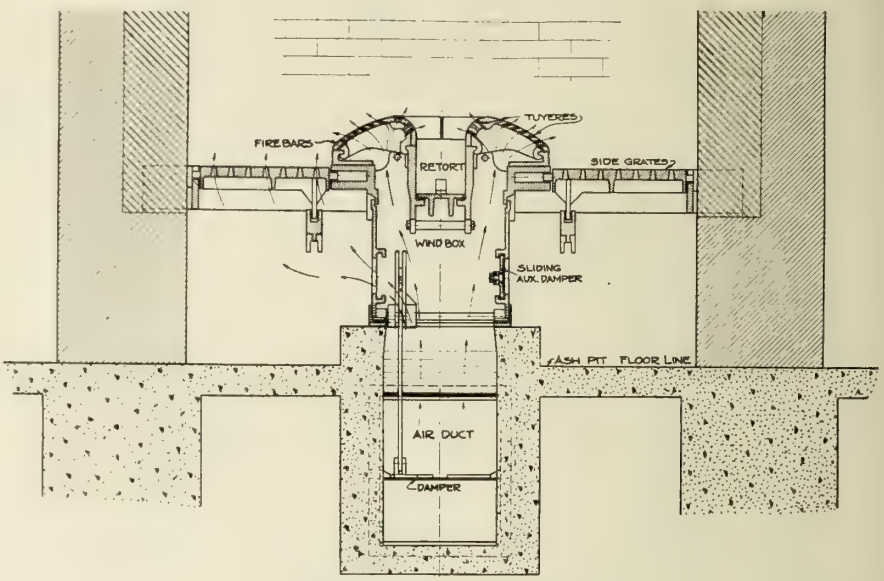
The Underfeed Stoker

The underfeed stoker is in general a forced draft arrangement, the fuel in this type of stoker being in a very thick mass, through which the air for combustion must be forced. The usual arrangement is a trough in a ram moved backward and forward by means of a piston contained in a cylinder outside the boiler setting. On top of this cylinder and directly communicating with the trough is the coal hopper. The action of the stoker is to push the charge of green coal into the bottom of the retort, underneath the glowing coal on the top of the retort. The volatile gases are immediately distilled from the green coal and passing up through the glowing bed above are thoroughly ignited and complete their combustion as they pass under the heating surface. The solid carbon is ignited and in turn pushed up to the top of the retort by the fresh incoming charge of coal. The ash and clinker fall onto the side plates and are gradually worked along to the back of the furnace and dumped into the ashpit, or in some cases are drawn out through the furnace doors by hand. Air is supplied through tuyeres at the side of the retort.

Quite a large number of different makes of the underfeed stoker are available, but they differ mostly in detail. The principle of underfeed stoking is that the green coal is placed directly on to the grate underneath the mass of incandescent carbon, instead of being thrown on top of the burning coal as in ordinary firing. In this way a chain grate can really be considered as an underfeed stoker, although the name is usually reserved for the type of stoker which has a ram for pushing the green coal onto the bed and under the burning coal above.



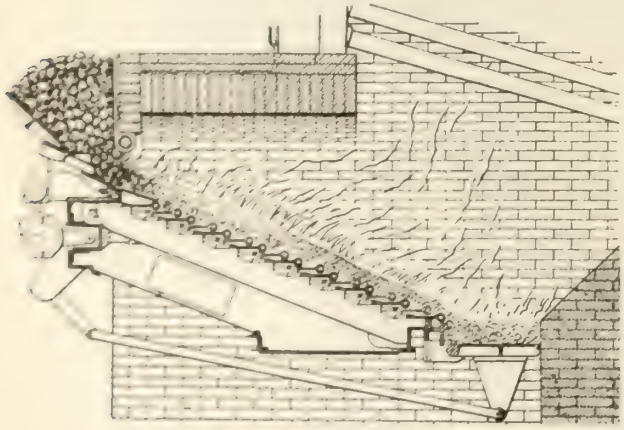
Longitudinal Section Type K Stoker



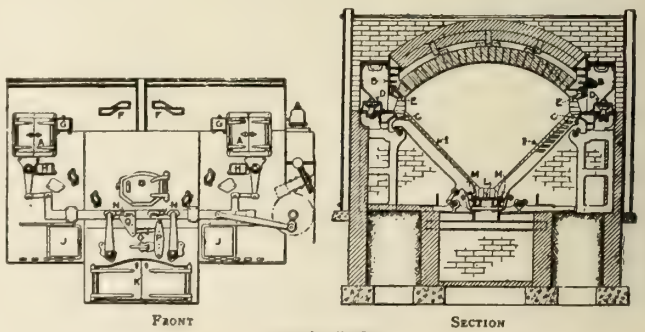
Cross Section of Type K Stoker

Overfeed Stokers

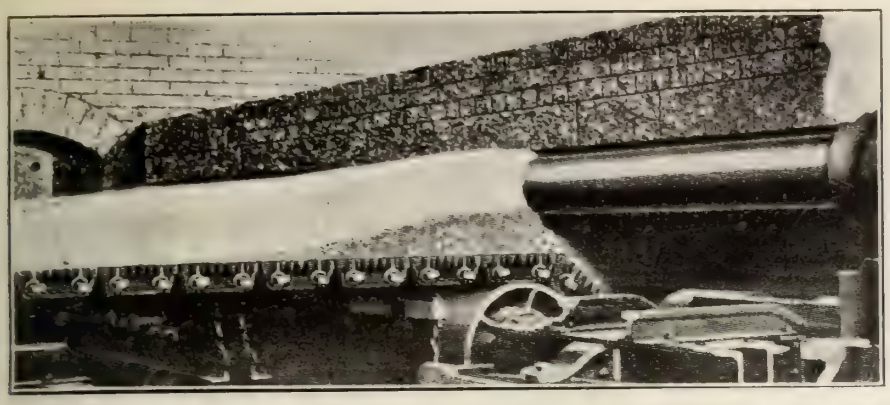
In the overfeed type of stoker, the grate is set at an angle of about 60 degrees forming a V shaped furnace. Over suspended an arch of refractory material, or faced with refractory material. Fuel is fed into the grate through openings at the side and top of the grate. Air is supplied through openings in the arch and also through the lower part of the grates. Slight movement of the inclined bars and the force of gravity cause the coal to travel from the top to



Lehigh Stoker For Forced Draught



Detroit Stoker



Green Chain Grate Showing Waterback

the bottom during the process of combustion, and in the bottom of the V there is usually an arrangement for breaking the clinker and enabling it to be dumped into the ashpit underneath. The coal as it is fed onto the grate at the top comes under the influence of the refractory and the volatile gases are distilled off and ignited, the remaining solid combustible passing slowly down the grate until it reaches the bottom as incombustible.

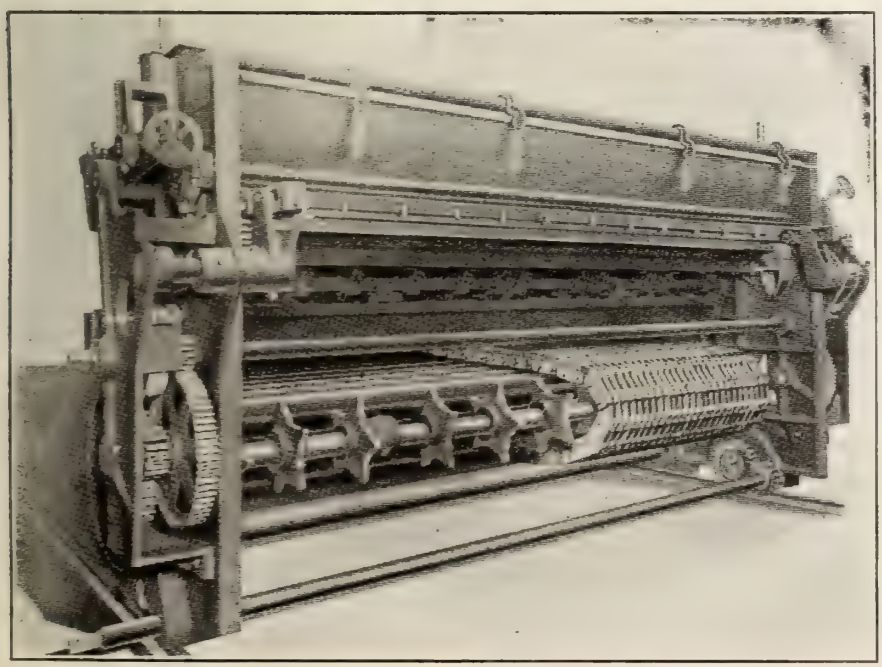
Work of Manufacturers

To the stoker manufacturers in general, engineers owe a pretty considerable debt. They have in the course of their investigations cleared up many points in the science of combustion of fuel under boilers that were not clear. They have materially aided the conservation of natural resources by continually striving to promote more efficient combustion. The continued success in developing efficient stokers has spurred on the manufacturers of refractories to produce a setting that will stand up under the high temperatures now produced in furnaces. The mechanical stoker has made possible the large boiler unit and the high over ratings which enable a plant to operate under excessive loads with a normal investment in boiler plant.

The Stoker Manufacturers Association which includes the manufacturers of all the better known types of stoker, are doing a good work by collaborating together in research and sharing experiences, all of which is to the general good of the steam engineering world.

BRITISH ELECTRICAL RESEARCH

While an increasing amount of electrical research work continues to be done by individual electrical engineering firms in Great Britain, co operative research is being developed on an ambitious scale. The Research Association formed by the British Electrical and Allied Manufacturers is expending £8,000 a year for 5 years on this type of research, which is aimed at the benefit of all concerned in the electrical industry. This financial arrangement was made at a time of acute depression in the world's trade and it will probably be greatly bettered when conditions improve. While this sum in itself may not appear large, British research workers have the faculty of getting very valuable results from a very moderate expenditure. The Royal Institution of Great Britain, in which Humphrey Davy, Faraday, Dowar and other famous scientists made their valuable discoveries, did not expend much more than £100,000 on research over a period of 100 years. Practically every leading section of industry in Great Britain has its organised co-operative research association. In the case of brass, copper, and other metals not containing iron, a great deal of very interesting research is now being carried on. The casting of brass, the influence of impurities on the working of copper, the electric melting of non-ferrous metals, and the grinding, jointing, and polishing of such metals are being closely studied. Perhaps the most important part of this research lies in the investigation of corrosion. The production of rustless iron and steel has stimulated the brass and other industries to give attention to the causes of corrosion. It is stated that the examination of tarnishing, which is the first stage towards corrosion, has already yielded very interesting results.



Green Chain Grate Showing Driving Mechanism.

BURNING BROWN COAL

Valuable deposits of brown coal and lignite are found in various parts of the world, and a great deal of scientific attention is being given to the problem of utilising them to the best advantage. In no other country have the problems of economical fuel consumption been more successfully studied than in Great Britain; and it is only natural that British engineering firms should have recently devised special boilers and furnaces for the efficient burning of brown coal. A trial installation in which the usual arrangements for burning ordinary coal were ingeniously modified, was set up recently in a British factory and exhaustively tested with very promising results. The object of the apparatus is to improve or raise the grade of the coal before it is actually fed on to the grate. The fuel passes through a special apparatus for a period of 45 minutes, during which it is exposed to hot gases which drive off the greater part of the moisture and the carbon dioxide. The result is a fuel of a much greater steam producing value than the original coal.

The Combustion Equipment Co., Kent Building, have been appointed agents for the Graver type K water softener, a product of the Graver corporation, East Chicago, Ind.

A 20-page booklet has been published by the Hydraulic Society, New York, entitled "Trade Standards in the Pump Industry." This work explains what is meant by trade pumps. plain fitted pumps, or brass fitted pumps; what is considered standard equipment for trade pump and what are considered extras; typical sizes of trade pumps are shown and definitions are given of terms used in the industry such as static head, total dynamic head, static suction lift, dynamic suction lift, etc. The booklet is recommended by the society as a guide to pump users.

Underfeed Stokers In Harvester Plant

Steam is Used for Both Power and Process Work in This Hamilton Plant. The Coal Handling, Storage and Ash Disposal Arrangements Are Well Designed and Convenient

THE FOLLOWING description of recent additions to the power house equipment of the International Harvester Company of Canada at their Hamilton works, will no doubt prove to be of interest.

The power plant at present in use was erected in 1912 and at its inception was used as an auxiliary plant, ample provision being made, however, for additional equipment necessary at such time as the old power house was discontinued, also to take care of future expansion.

During the past year additional steam generating equipment has been installed and at the same time an endeavor has been made to bring the coal and ash handling system thoroughly up to-date.

Having in mind the rapid progress made in power house equipment during the past few years, no attempt will be made to describe the equipment in detail with the exception of that which has been recently installed.

The power plant, centrally located east and west, is situated towards the south end of the property, the natural course of any future expansion being in this direction. It consists primarily of an engine room and boiler room and has overall dimensions of 105 ft. x 105 ft. It is of steel and concrete construction with the exterior walls of pressed brick trimmed with stone and whilst of pleasing appearance, utility has been the keynote of its construction. The transformer room, accessible from the engine room, is a separate structure. The pump room is in the basement under the engine room. In the boiler room, steel stairways and galleries give ready access to all pipe lines, boiler tops and the overhead bunker, coal conveying and distribution equipment.

Original Equipment

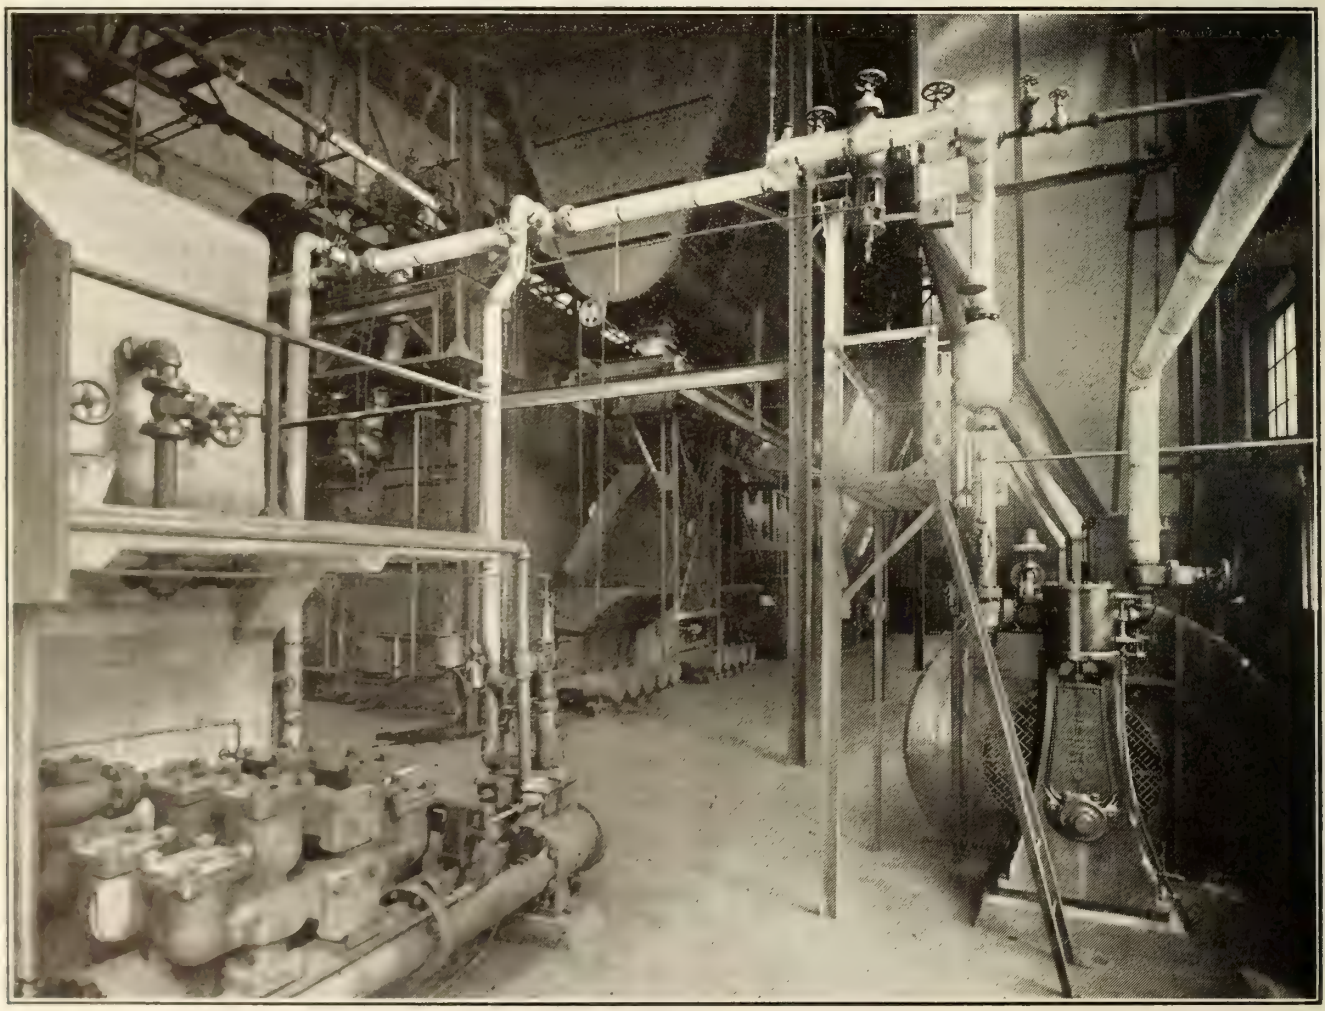
The initial steam generating equipment consisted of two type 30 Stirling boilers, each with a heating surface of 4000 sq. ft., 420 3¼ in. tubes and 7 in. steam outlets. These units are equipped with B. & W. cored type superheaters and Dutch ovens with grate areas per boiler of 89 sq. ft. and are designed to burn both coal and wood refuse from the wood shop, have a working pressure of 150 lbs. gage and a nominal rating of 400 h. p.

Electric energy can be generated when occasion requires but normally the steam generated is used for heating, the operation of air compressors, steam hammers, the heating of water for domestic purposes and the operation of many pieces of auxiliary apparatus installed in and about the power house.

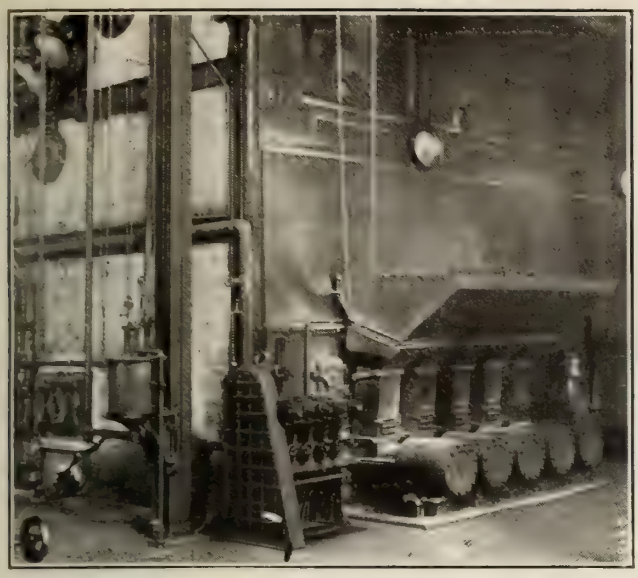
An auxiliary steam generating unit is provided by means of a Wickes waste heat boiler, of a nominal horse power of 400, in connection with the malleable foundry.

Coal Storage

The coal storage area is situated on the east side of the power house, the unloading and reclaiming of the coal be-



General view showing boiler room arrangement.



Showing Stoker control and five retort stoker and damper regulator.

Front view of stoker installed by Underfeed Stoker Co. of Canada.

ing taken care of by a traveling electrically operated Shaw crane, operating a clam shell bucket, the crane is of 3 tons capacity and has a span of 75 feet and a length of 250 feet.

Cars delivering the coal are run over a reinforced concrete dumping pit, and there emptied, the pit having a capacity of two cars, the coal may then either be delivered to the bunker or to the storage area. The plant locomotive also obtains its supply of fuel from this source. A fence 6 ft. high has been constructed around the storage area and by this means all coal in storage is kept within the range of the crane and no trimming is necessary.

The capacity of the area available for coal storage is about 4,500 tons all readily accessible to the clamshell bucket operated by the crane.

At the western extremity of the coal storage area is situated the coal crusher and conveying equipment. A steel hopper 10 ft. x 10 ft. in plan delivers the coal to a reciprocating plate feeder, which in turn feeds a single roll crusher 30 in. x 30 in. The plate feeder is driven by chain and sprockets from the crusher roll shaft. The crusher operates at a roll speed of 50 r. p. m. and is driven by a 30 h. p. motor. The outlet from the crusher discharges upon an apron conveyor 33 ft. in length operating at a speed of 100 f. p. m. and like the plate feeder is driven from the roll shaft of the crusher. The apron conveyor discharges into the boot of a centrifugal discharge elevator. This elevator is on 39 ft. centres, operates at a speed of 200 f. p. m. and is made up of 14 in. x 7 in. steel buckets spaced 24 in. on centres, this elevator in turn discharges into a spiral conveyor; this conveyor is 86 ft. in length and runs the length of the boiler fronts, being suspended to the upper members of the roof trusses, the spiral is 12 in. in diameter and operates at a speed of 75 r. p. m., suitable outlets are provided for filling the coal bunker. The capacity of this equipment is 25 tons per hour.

The overhead coal bunker is of steel and of 100 tons capacity and is situated directly across the fronts of the coal burning boilers; a traveling weigh lorry having a capacity of 1500 lbs. runs directly beneath the bunker and is used to weigh and deliver the coal to the stoker hoppers. Should it be desired to feed coal to the wood refuse burning boilers this can be readily obtained from the weigh lorry by means of a portable chute on wheels so that the only hand labor is that occasioned in feeding the coal to these furnaces.

The New Plant

The new steam generating equipment consists of two Stirling water tube boilers, type S 21, each with a heating surface of 4135 sq. ft., 8 in. steam outlets and B. & W. cored type superheaters.

These units are equipped with 5 retort Jones A. C. underfeed automatic cleaning stokers with active grate areas per boiler of 80.1 sq. ft. and a capacity of 2,200 lbs. of coal per hour at 150 per cent. capacity; have a nominal rating of 413 h. p. and are designed and constructed for a working pressure of 150 lbs. gage. A brief description of the stoker automatic control follows:

The coal is forced into the furnace below the live fire bed by steam operated rams whose actions are governed by a special valve known as the Cole automatic valve; which allows of individual control, either automatic or by hand, of the feed to each retort, these retorts being spaced 20 inches on centres across the width of the furnace. The setting of the valves, which is done by hand, adjusts the number of strokes of each ram in relation to a fixed speed of the worm drive actuating the valves. The speed of this worm drive, which is belt driven from the shaft of the forced draft fan, is therefore governed by the speed of the fan engine which is in turn automatically controlled by a fan engine regulator according to the variations in the steam pressure.

In this way the cycle is complete, any reduction in steam pressure increases the speed of the fan engine, thereby increasing the quantity of air delivered to the furnace and at the same time increasing the quantity of coal fed to the furnace. This condition exists until the loss of pressure is made up, when normal operation automatically ensues.

In the furnace the coal is forced upward and backward during the process of combustion until it reaches the balanced dump plate at the rear of the furnace, in the form of ash and clinker, and at this point the automatic control ceases.

From the dump plate the furnace refuse is dumped into the ash pit, accessible from the basement, sprayed from a pipe line situated immediately below the dump plate and allowed to cool.

The forced draft employed in connection with the stokers for these boilers is supplied by one extra heavy steel plate blower, capable of delivering 30,000 cu. ft. of air per minute when driven at a speed of 440 r. p. m. by a 9 in. x 8 in. vertical self oiling steam engine. This fan which is under automatic steam control, discharges into a concrete duct having a sectional area of approximately 12.5 sq. ft. and thence into a metal duct connecting with the air chambers under the stokers. The static pressure is 4 inches of water.

Control of the furnace draft through manipulation of the stack damper is effected by means of a hydraulically operated damper regulator. The control exerted by this regulator depends entirely upon the amount of negative pressure or vacuum existing in the furnace itself and not on the variations in the steam pressure. Consequently there is a positive movement of the damper in direct relation to the needs of the furnace for

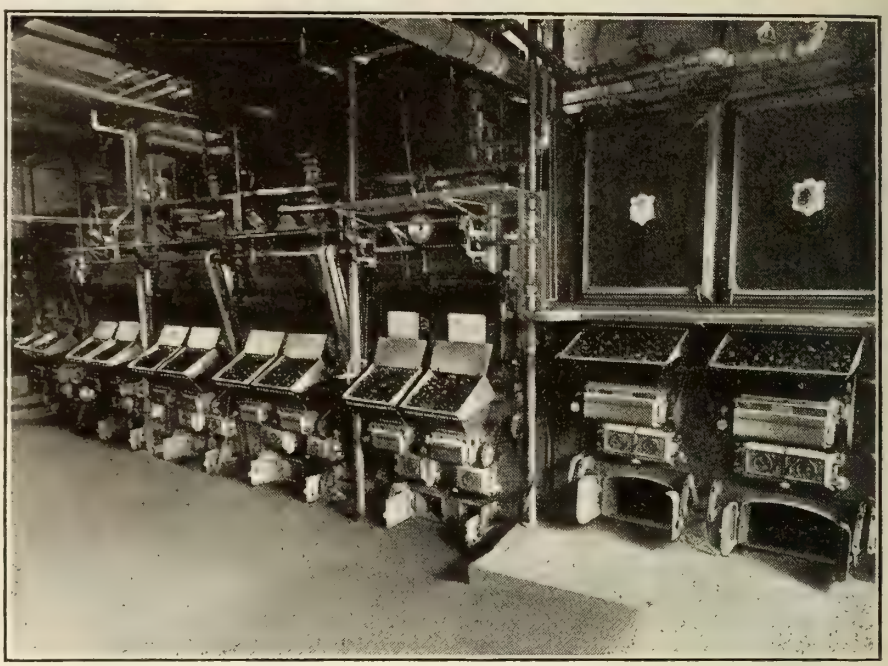
Sprinkler Stokers In a Mill Power Plant

A Type of Stoker Readily Adaptable to Any Boiler, Requiring no Alterations of Furnace Brickwork or Ashpits. A Thin Even Fuel Bed is Attained by the Action of the Revolving Blades

IN DISCUSSING the various styles of stoker in another article in this issue, the sprinkler type is referred to as being of a nature suitable for small installations, on account of its moderate cost. This makes it possible to instal a mechanical stoker in a plant which perhaps could not be made to show a profit on the installation of a stoker requiring special brickwork setting and arches. The sprinkler stoker, referred to in this article, does not require any special setting, and can be readily applied to any type of boiler without structural alterations being necessary.



Installation at Western Canada Flour Mills.

Constructional Features

The "Canada" stoker, manufactured by the Canada Stoker Co., Galt., consists essentially of a hopper containing a reciprocating feed plate actuated by an eccentric. The coal in the hopper works down due to the motion of this feed plate, until it reaches a flat plate or table, formed as an integral part of the stoker. In front of this table are a set of revolving blades, driven by the stoker mechanism, which catch the coal as it is pushed along the table, and due to their motion, fling it out over the surface of the grate in an evenly distributed stream. The feed plate has a catch which enables it to be stopped and started at will. The revolving blades have only to throw the coal that reaches them, the feed being regulated entirely by the feed plate.

The illustration makes the manner of distribution clear. There are one or two points which cannot be shown in an illustration of this kind. For instance, there is a curved plate concentric with the blades, and open on the side next to the furnace. This plate can be moved on its centre so as to bring the opening to the furnace either higher or lower, and in this manner give an adjustment which determines the longitudinal distance which the coal will be thrown. The curvature of the blades is such that the width of the furnace is effectually covered. The result of feeding the coal in this manner is to keep a bed of coal of about the ideal thickness, that is four inches, and furthermore it keeps it absolutely level. The absence of holes and hillocks in the fire, in conjunction with the ability to maintain a very light fuel bed, is a requisite of efficient combustion.
